S. = Streptomycin-sensitive. R. = Streptomycin-resistant.

by the more frequent isolation of streptomycin-resistant strains later in the investigation. This may be accounted for by survival of resistant strains only in patients under treatment or by cross-infection with a B.C.N. strain originally sensitive but resistant after treatment.

Bacteriological investigation thus would not seem to justify streptomycin therapy, though the presence of B.C.N. in a severe case of infantile diarrhoea and vomiting may be regarded as a warning signal and a pointer to a more serious prognosis.

Clinical improvement in some patients receiving the antibiotic seemed to be attained at a more rapid pace than in those treated by standard measures. Especially was this so in cases associated with a parenteral infection: stools returned to normal in a shorter time and the upward trend in the patient's general condition appeared steeper. In agreement with this are the favourable results recorded by Goettsch, Cobley, and Mulloy (1948) in their cases of parenteral gastro-enteritis.

In a number of our cases streptomycin was followed by a spectacular improvement—in others it failed completely. Even detailed analysis of the case histories has not furnished clinical or bacteriological indication for the use of the antibiotic. In each individual case the result of streptomycin therapy was also unpredictable.

Summary

The results of streptomycin treatment of infantile diarrhoea and vomiting are discussed.

Streptomycin was given to 26 cases orally, and to 24 intramuscularly, while a control group of 29 cases received no antibiotic.

The dosage of streptomycin was either 20 mg. per lb. body weight per day for five to seven days, or 600 mg. for the first 24 hours, followed by 450 mg. daily for a further four to six days.

The results do not indicate that streptomycin exerts any specific therapeutic effect.

The frequent association of a special type of *Bact. coli* (B.C.N.) with infantile diarrhoea and vomiting was confirmed, being found before treatment in 50 out of a total of 79 cases, but no evidence was obtained that it was of any aetiological significance.

Our thanks are due to Professor Gaisford for his encouragement and valuable criticism; to Professor Maitland for allowing facilities in the department of bacteriology and for help with bacteriological problems; and to Drs. S. K. Guthrie, R. I. Mackay, and N. Wells for permission to include some of their cases in our investigation

Food Investigation, 1947, is a report from the Department of Scientific and Industrial Research (H.M.S.O., price 6d.) which is written for the non-specialist. It describes work which has been done on whalemeat during an expedition to the Antarctic by the factory ship *Balaena*. It was found that the whalemeat was much improved in quality if the whale was bled and cooled down rapidly. The practice recommended was to make an incision in the main blood vessels in the neck and to slit the belly wall so that the cold sea-water could circulate. In this way the meat could be kept in good condition for 18 to 24 hours. Research on meat, fruit, and potatoes continued during the year, and at the Torry Research Station quicker and more convenient methods of freezing were studied. Lobsters are apparently better frozen cooked than raw. Rapidly frozen cooked lobsters can be stored for eight months with little change in flavour and texture.

THE AETIOLOGY OF GRAVITATIONAL ULCERS OF THE LEG

BY

S. T. ANNING, M.A., M.D., M.R.C.P.

Tutor in Dermatology, the University of Leeds

The term "gravitational ulcer," first used by Dickson Wright (1931), refers to those chronic ulcers which occur on the lower half of the leg associated with one or more of the following: oedema, cyanosis, induration, sclerosis, pigmentation, loss of hair, eczema, and varicose veins of the affected limb. These are signs of chronic impairment of the venous drainage of the leg. The importance of gravity in the cause of this condition was stressed by Brodie (1846) and by Hilton (1863). Brodie called such ulcers "varicose," and they have long been thought to be due to varicose veins. Gay (1868) was probably the first to show, by clinical observation and careful dissection, that many were due to obstruction of trunk veins, deep and superficial, and that varicose veins often play no part. Gay's work seems to have been forgotten or has been neglected, and the view that varicose veins are the main or only cause has persisted (McPheeters, 1928). Dickson Wright (1931) and Homans (1939) held this opinion, though both believed that some gravitational ulcers were due to thrombosis of deep veins. However, in a series of 432 patients with leg ulcers Birger (1941) found that thrombosis was the chief factor. Nilzén (1945) thought that certainly 41% or possibly 56% of such ulcers were caused by previous thrombosis, Bauer (1946) that 80–90% and Birger (1947) that 40% were due to this cause.

The belief that varicose veins play a major part in the aetiology of these ulcers has affected treatment, which until the last few years has concentrated attention on such superficial varicose veins as might be present.

Allen, Barker, and Hines (1946) considered that chronic venous insufficiency or stasis of the venous blood flow was due to obstruction of one of the main veins of the limb, particularly the ilio-femoral, as the result of thrombophlebitis, neoplastic invasion, or external pressure; incompetency of valves of the ilio-femoral vein resulting from thrombophlebitis without permanent obstruction of the vein; or varicose veins of primary type (i.e., developing spontaneously), particularly those of long standing or considerable extent.

The chief manifestations of chronic venous insufficiency are in the skin and subcutaneous tissue, and are thought to result from venous stasis rather than from increased venous pressure. As a result of stasis the venous blood has a low content of oxygen and a high content of carbon dioxide and other products of metabolism (Dickson Wright, 1931). The nutrition of the tissues is impaired and oedema and necrosis may result. Ulceration of a limb with venous stasis may occur at the site of a local thrombosis of small superficial veins or it may follow trauma with broken skin. The healing power of the poorly nourished tissues is affected and trauma may not be followed by repair. Hence ulceration is a common complication of chronic venous insufficiency. Infection plays little or no part in ulceration (though it may cause thrombosis). There is no relation between the type of infection or the bacteria in the ulcerating area and the slowness or rapidity with which the ulcer heals. Those ulcers which heal most rapidly often contain the most bacteria (Löwenfeld, 1924).

The importance or otherwise of varicose veins in causing chronic venous insufficiency and ulceration is still a matter of dispute. Certain it is that many individuals with severe varices do not suffer from either. Furthermore, patients with chronic venous insufficiency and ulceration of the leg are seen not uncommonly with no varicose veins visible or palpable.

The venous circulation of the limbs can be investigated by clinical examination, including the patient's history, the condition of the limbs, certain special tests (the Brodie-Trendelenburg, Perthes's, etc.), phlebography, venous pressure estimations, examination of veins after surgical removal, and post-mortem dissection.

Present Investigation

This investigation was undertaken to try to determine the cause of ulceration in a series of 270 unselected patients examined and treated personally. The methods employed were clinical, with phlebography in a few patients.

The term "thrombosis" is used here to denote thrombosis of one of the deep veins of the lower limb, and is assumed to have taken place if there is a history of chronic oedema of the leg of sudden onset, with or without pain and tenderness in the calf and with other signs of persistent venous stasis. Symptoms of pulmonary embolism at the onset and the appearance of varicose veins soon after are taken to indicate that thrombosis occurred.

There were 192 female and 78 male patients. Their age at the onset of ulceration varied greatly. One woman who had suffered from osteomyelitis of the left leg when aged 7 first developed an ulcer in that leg after slight trauma at the age of 13, and another first developed an ulcer at 17 years while suffering from congenital haemolytic icterus. Ulceration occurred in one youth of 17 a year after Trendelenburg operation. Most ulcers appeared during the fourth and fifth decades, but in one patient not until the eighth.

Family History.—Patients were questioned about the presence of varicose veins or ulceration of the legs in their parents, brothers, sisters, or children. Twelve patients were uncertain and 140 (54%) of the rest gave a positive family history.

Illustrative Cases.—Three sisters (unmarried) had gravitational ulcers. Their mother, one of their four brothers, and another sister (married, with five children) had ulcers. Four other sisters were unaffected.

A tram driver had gravitational ulcers. Both his parents had varicose veins and two maternal aunts had ulcers.

Heredity may play a part in the aetiology of ulceration of the legs associated with purpura haemorrhagica, sickle-cell anaemia, congenital haemolytic icterus, splenic anaemia, Gaucher's disease (Witts, 1942), or Cooley's anaemia (Este, Farber, and Stickney, 1948); otherwise its importance in this condition is not well established. Weber, Rast, and Lutteroti (1930), however, described chronic ulceration of the legs following pneumonia in a man of 25 with thrombo-angiitis obliterans whose father had suffered from similar ulcers, and Carleton (1948) showed a striking family history in two sisters with varicose ulcers. Congenital absence of valves in the veins of the leg as described by Eger and Casper (1943) and Curtis and Helms (1947) may be important in relation to inheritance. Weber (1948) wrote that *there certainly is a constitutional tendency to ulcus cruris* in some families.

Occupation.—Table I shows the occupations followed at the time ulceration appeared. It will be noted that very

few patients had sedentary jobs, and that many worked standing with little activity as in fitting, drilling, shopkeeping, weaving, and spinning. Although many miners attend this hospital, only one was seen with a gravitational ulcer. Constant muscular effort while working, standing, kneeling, or lying may prevent venous stasis.

Child-bearing.—Of the 192 women, 37 (19%) were nulliparous. The remaining 155 had 1 to 15 children each (mean 4.1).

Weight.—Obesity has been thought to be of importance in relation to gravitational ulcers (Dickson Wright, 1931; Heller, 1943; Mahorner, 1949). The weight of patients in this series varied between 45 and 132 kg.: a distribution curve is shown in Fig. 1. Nine men and 29 women weighed more than 89 kg., and, of these, four men and twelve women weighed more than 100 kg. One woman weighed 132 kg. It would appear that in the majority of patients with ulcers obesity plays no part in the aetiology.

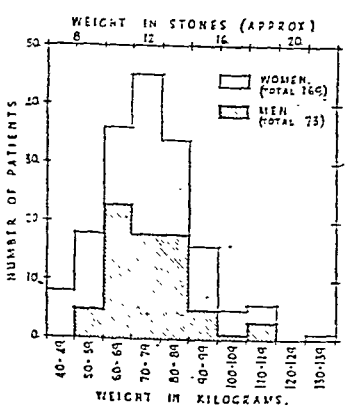

FIG. 1.—Distribution curve of body weight.

Blood Pressure.—The blood pressure of 69 men and 172 women was determined. The readings of the women were classified in age groups. The number with systolic pressures above 140 mm. and diastolic pressures above 90 mm. is shown in Table II, with the total in each age group, in order to compare the results with the figures given by Robinson and Brucer (1939) based on a group of 3,405 American urban women taken at random. The proportion of ulcer patients with hypertension is significantly higher than in the control group. The men with ulcers formed a group too small for conclusions to be drawn from their blood-pressure readings.

TABLE II.—*Proportion of Women with Hypertension (172 Patients)*

Age Group:	25–9	30–4	35–9	40–4	45–9	50–4	55–9	60–4	65–9	70–4
Total in group	3	4	13	17	20	30	23	32	12	13

Diastolic hypertension:										
No. in group	0	1	2	5	5	11	14	21	10	9
Percentage of group	—	—	15·3 (5·1)	29·4 (9·1)	25·0 (11·5)	36·6 (10·9)	59·0 (19·9)	65·6 (22·5)	83·2 (25·0)	69·2 (12·5)

The figures in parentheses are those of Robinson and Brucer, 1939.

Concurrent Disease.—The following diseases were present in addition to ulceration: pernicious anaemia in one patient, severe anaemia secondary to menorrhagia in one, congenital haemolytic icterus in one, diabetes mellitus in four, hyperthyroidism in one, hypothyroidism in one, thrombophlebitis migrans in one, Paget's disease (osteitis deformans) in two, and syphilis in two. The ulceration of the legs of the last two patients had none of the characters of syphilitic ulceration, and antisyphilitic treatment did not cure the ulcers. The Wassermann reaction was also determined in 68 other patients, and was negative. Some of the aetiological factors as disclosed by the history in the present series are shown in Table III.

Stasis due to Thrombosis of Deep Veins

1. Post-partum "White Leg"

Sixty-nine (36%) women gave a history of post-partum "white leg" (phlegmasia alba dolens)—28 after the first confinement. In the remainder the "white leg" occurred after confinements varying from the second to the thirteenth. Most of the women were multiparae (mean 3.9 confinements), and in six "white leg" occurred after two confinements; in one patient it occurred three times. The mean age at which thrombosis took place was 30.2 years (variation 19 to 46 years). In 27 patients the thrombosis was bilateral and in the others it occurred slightly more commonly on the left side. Only 13 women developed "white leg" after a normal confinement, and one of these got up on the third day, "white leg" developing soon after. Intervention with forceps took place in 18 patients, severe post-partum haemorrhage in 12, a long labour in five, twins in three, abortion at seven months in two, toxaemia of

pregnancy in two, malposition in two, retained placenta in two, ante-partum haemorrhage in one, and triplets in one. Details of other abnormal confinements were not obtained. Matthew (1947) mentioned the raised incidence of "white leg" with high forceps deliveries and stressed the role of infection in some cases. The first ulcers in the present series occurred three months to 27 years after the "white leg" (mean 8.9 years).

Illustrative Case.—This patient was delivered of her only child at the age of 25. Details are not available, but she says that it was a difficult labour and forceps were used. A few days later she had "white leg" and "pneumonia" (probably pulmonary embolism). The swelling of the legs persisted, and ten years later, following slight trauma, the first ulcer developed. There was no family history of varicose veins or ulcers of the legs. Her weight was 85 kg. No varicose veins were found on examination, but the legs were oedematous, indurated, and pigmented over the lower halves.

2. Ante-partum Thrombosis

Fifteen patients gave a history of pain and swelling of one or both legs of sudden onset during pregnancy. Oedema of the affected legs persisted and some of the patients developed varicose veins for the first time. It is assumed that thrombosis of the deep veins of the leg had occurred, and in seven patients ulceration of the leg followed within a few weeks. Ante-partum thrombosis is well recognized as a complication of pregnancy, but, as Matthew (1947) pointed out, it is less frequent than post-partum "white leg."

Illustrative Case.—A spinner had bilateral varicose veins from the age of 18. Her mother also had varicose veins. At the age of 44, at about the sixth month of her eighth pregnancy, she developed "white leg" (left). She spent the remainder of the pregnancy in bed. An ulcer of the left leg appeared a few months later. She weighed 97 kg. and her blood pressure was 240/110 mm. when she was examined at the age of 52.

3. Conditions Affecting the Leg

Injury to Leg without Fracture.—Sixty patients had suffered such an injury to one or both legs. The severity varied from that of a kick to that of a fall from a height, as from a roof or down stairs or through a floor which collapsed (three patients). Other injuries were due to a fall from a tram-car, a superficial gunshot wound of the leg, or wrenching an ankle; many were caused by mild blows such as walking against some firm solid object. In many the skin had not been broken. With most ulcers of the leg the precipitating cause is mild injury with abrasion of the skin. In the group under consideration, patients with a previous history of thrombosis of the leg in whom mild injury produced ulceration are not included. Only those with legs previously normal or with varicose veins with no evidence of chronic venous insufficiency are considered. Of these, 23 gave a history of swelling of the leg after the injury, probably due to thrombosis caused by the injury, and 10 developed varicose veins after the injury, possibly from the same cause. At the time of examination, when ulcers were present, 52 had varicose veins, which in several patients were in the injured leg alone. Slight or moderate injury to the leg with laceration, soft-tissue wounds, or simple haematoma may result in thrombosis. Vance (1934) investigated thrombosis of the veins of the lower extremity and pulmonary embolism as a complication of trauma. He found that even minor injury to the leg may result in thrombosis. Homans (1934), Bauer (1944), Birger (1947), and Mahorner (1949) are in agreement with this view. In Bauer's patients the presence of thrombosis was confirmed by phlebographic examination.

Illustrative Case.—A grinder in good health was injured at the age of 32 by a severe blow from an iron girder which fell against his right leg. There was no fracture and the skin was not broken. Swelling of the leg followed. Varicose veins appeared for the first time, and a year later there was ulceration of the affected leg. At the age of 34 the varicose veins were ligated, but the ulceration was not improved. The Wassermann reaction was negative. His father had suffered from ulcers of the leg.

Injury to the Leg with Fracture.—This had occurred in 11 patients—affecting the tibia and fibula in six, the femur in two, the patella in one, and the ankle (fracture-dislocation) in two. Both direct injury to a vein and immobilization of the limb may have been factors in causing the thrombosis which followed. Ulceration occurred in a period varying from one month to 26 years (mean 4.8 years) after the fracture.

Illustrative Case.—A married woman sustained a fracture-dislocation of the right ankle at the age of 37. The leg was immobilized in plaster-of-Paris for three months, after which it was found to be oedematous and discoloured. These signs persisted, and one month after removal of the plaster ulceration of the leg occurred. There was no family history of ulcers or varicose veins.

Operation on a Leg.—Six patients had undergone operation for knock-knee, for hammer-toe, for deformity of the tibia in Paget's disease, for tuberculosis of bone, for osteoarthritis of the hip, and for an unknown cause. In each patient thrombosis of the affected leg had followed the operation, ulceration occurring later.

Infection of the Leg.—Fifteen patients had infection of the leg in various forms causing thrombosis: osteomyelitis (2—one of the tibia and one of the patella), septic wounds of the leg (12), and abscess of the ankle drained with tubes (1). One of these patients was a diabetic. Ulceration followed the infection in a period varying from a few weeks to 11 years (mean 4.1 years).

Illustrative Case.—A motor mechanic aged 57 caught his left ankle against a sharp piece of metal, an abrasion resulting. This healed, but two weeks later an abscess formed at the site of injury and burst, discharging pus. At the same time the whole leg became swollen, with deep tenderness in the calf. He attended the clinic five months later with an ulcer at the site of the abscess and with oedema and discoloration of the leg. The other leg was normal except for varicose veins, which were prominent in both legs.

Treatment of Varicose Veins.—This appeared to be the cause of ulceration in 15 patients, including two in whom the injection of varicose veins was carried out during pregnancy. In two others thrombosis of the leg had occurred previously, in one after a fracture of the patella and in another after a fracture of the humerus which required rest in bed. Injection of varicose veins seemed to intensify the chronic venous insufficiency already present in these patients and to produce it in the remainder. Ulceration of the legs concerned resulted within a few months. The risk of thrombosis of deep veins after the injection of sclerosing fluids into superficial varicose veins, especially above the knee, was stressed by Boyd and Robertson (1947). In three of the patients in the present series varicose veins had been injected at the same time as the internal saphenous vein was ligated, ulceration following within a few weeks. In none had phlebography been carried out to determine the state of the deep venous circulation of the legs before injection of the varicose veins.

Illustrative Case.—A married woman suffered from "white leg" (left) after her first confinement at the age of 28, when forceps were used. Varicose veins followed, and these were

injected eleven years later. The left leg became even more oedematous, and ulceration occurred shortly after. Her mother had suffered from varicose veins and ulcers of the leg.

4. Thrombosis of Unknown Cause

Thrombosis in the legs from no apparent cause occurred in 19 patients. In several the condition had started in superficial veins, but all gave a history of marked oedema of the affected leg, with pain in the calf in some, which suggests that the deep veins were involved. Thirteen patients had a family history of varicose veins or ulcers of the legs. Phlebography confirmed the presence of thrombosis (of the femoral vein) in one patient.

Illustrative Case.—A nulliparous woman weighing 76 kg. and living an active life suffered from phlebitis of a superficial vein of the left calf for no apparent reason at the age of 36. Within a few days the leg became greatly swollen and pulmonary embolism occurred. Shortly after this the right leg also became swollen. When she was able to walk the oedema increased and ulceration near the left ankle followed. Her mother had suffered from varicose veins and ulcers of the leg.

5. Thrombosis due to Recumbency or Inactivity

Medical Illness.—Some illness, the disease itself or the rest in bed necessitated by it, had caused thrombosis of the legs in 12 patients. In three it was said to have been influenza, in two bronchitis (one with pleurisy), and in two lobar pneumonia. Rheumatoid arthritis with many months in bed, pyaemia following a carbuncle, tonsillitis, scarlet fever, and pyrexia of unknown origin were each responsible in the other patients.

Illustrative Case.—A baker whose mother had varicose veins developed scarlet fever at the age of 17. Three weeks after the onset, while in bed, thrombosis of the left leg occurred. There were no other complications of scarlet fever. An ulcer of the same leg appeared a few weeks later when he got up. The Wassermann reaction was negative.

Operations not on the Leg.—Twelve patients gave a history of "white leg" appearing shortly after an operation. Of these, nine had undergone an abdominal operation—two for appendicectomy (one with drainage), two for removal of ovarian cysts, one for cholecystectomy, one for hysterectomy, one for pelvic abscess, one for abdominal hernia, and one for an operation following an injury, the details of which are not known. Two patients had undergone left inguinal herniotomy and one a perineal operation of unknown type on the bladder for retention of urine. Allen, Barker, and Hines (1946) showed that post-operative thrombosis is more common after pelvic operations than after any other procedure, and more common in the left leg than in the right.

Illustrative Case.—A railway plate-layer underwent an operation for left inguinal hernia at the age of 37. Five days later he suffered from pulmonary embolism and shortly afterwards his left leg became swollen. Ulceration of the leg occurred a few weeks after he got up.

6. Thrombosis due to Miscellaneous Causes

Thrombosis of the leg occurred in a woman aged 29 during intravenous therapy with glucose-saline for hyperemesis gravidarum. An ulcer of the ankle followed at the site of injection. The risk of this complication of intravenous therapy when given at the ankle is now recognized.

A woman weighing 117 kg. had varicose veins for years, for which several injections with sclerosing fluids had been given. Thrombosis and ulceration followed a second-degree burn of the right leg. In another woman, aged 59, these followed a scald of the leg.

A miner aged 39, in bed on account of a slight injury to his back, had a thrombosis of the right leg, and ulceration occurred when he got up. He had injured his right groin when 27 years old and some swelling of the leg had followed.

A joiner aged 57 fractured his pelvis. Thrombosis and ulceration of the right leg followed. His mother had varicose veins and his brother an ulcer of the leg.

A farmer, when aged 22, had both legs severely bruised by a riding accident and varicose veins appeared. A year later Trendelenburg's operation was carried out bilaterally, marked swelling of the right leg occurring afterwards. At the age of 24 the varicose veins, which had reappeared, were injected with sclerosing fluid. Ten years later he fractured his right femur, the limb being immobilized for ten months with a plaster spica. Shortly after the plaster was removed the first ulcer appeared. The Wassermann reaction was negative. There was no family history of varicose veins or ulcers.

A labourer aged 58 had no family history of varicose veins or ulcers. When aged 27, while wearing puttees in the infantry, thrombosis occurred in the right leg with much swelling and aching. Varicose veins appeared for the first time, with ulceration, after a few months.

A Czech fur-cutter, a cigarette smoker, had suffered from thrombophlebitis migrans since the age of 21, with recurrent idiopathic thrombophlebitis of the superficial veins of the legs and right arm. No signs of arterial disease were present. There was marked venous stasis of the legs, with varicose veins. Ulceration first occurred when he was aged 31. His Wassermann reaction was negative and his weight 74 kg. His father and sister had ulcers of the legs.

7. Silent Thrombosis

When a patient has venous stasis, with no history of thrombosis, a silent thrombosis may be suspected if there has been pulmonary embolism; otherwise it may be indicated by phlebography, by surgical exploration, or by post-mortem examination. In this series, in those patients with no history of thrombosis, phlebography was carried out in only one, and of the others some may have had a silent thrombosis.

Illustrative Case.—The mother of 13 children, weighing 82 kg., had bilateral varicose veins for many years, and these were injected when she was 42. Her sister had ulceration of the leg. There was no history of thrombosis at any time and she had never been in bed on account of illness of note or operation, nor had she suffered any injury. The Wassermann reaction was negative. The first ulcer appeared in the right leg at the age of 51. Nine years later a phlebogram showed blockage of the deep veins of the right thigh near the knee

Venous Stasis with No History of Thrombosis

In addition to the patient mentioned above there were others with no history of thrombosis.

1. Venous Stasis due to Varicose Veins

There were 29 patients whose venous stasis and ulceration might have been due to varicose veins. Of these, 24 were women, of whom 17 were parous. In the whole group the family history of two was uncertain, but 17 of the remaining 27 gave a family history of varicose veins or ulcers of the legs or both. The age at which ulceration occurred varied from 20 to 78 years (mean 45.4 years). All but one had suffered from varicose veins for many years before ulceration appeared, and the problem arises whether these are cases of true varicose ulcer—i.e., ulcer due to varicose veins—or whether they are post-thrombotic, the thrombosis having been symptomless. Some of these patients had ulcers "riding" over a vein, to use the description applied by Homans (1939) to true varicose ulcers. The possibility of previous thrombosis in the other patients remains. The question of varicose ulceration is discussed later, but even were it assumed that most of the patients

in this group suffered from varicose ulceration they represent less than 11% of the whole series.

A tram driver weighing 84 kg., with a striking family history of varicose veins and ulcers of the leg, had varicose veins from the age of 12. An ulcer appeared on the right leg when he was 20 and on the left leg when he was 26. There had been no history suggesting thrombosis. Bilateral injection of varicose veins with sclerosing fluid was carried out when he was 20, and ligation and injection of the veins when 26, on both occasions after the ulcers had appeared. The veins were injected again when he was 29. The Wassermann reaction was negative. The early ulcers in this patient would seem to have been true varicose ulcers.

A mother of five children, who had been a baker, developed varicose veins at the age of 26 while bearing her first child. There was no family history of varicose veins or ulcers. One of the veins burst when she was 42 and an ulcer formed at the site. The varicose veins were treated by operation soon after with no benefit to the ulcer, and were injected when she was 50. Tremendous swelling of the leg resulted, no doubt due to a thrombosis of deep veins. She now has calcification of the varicose veins, much induration of the legs, and diabetes. Her weight is 76 kg.

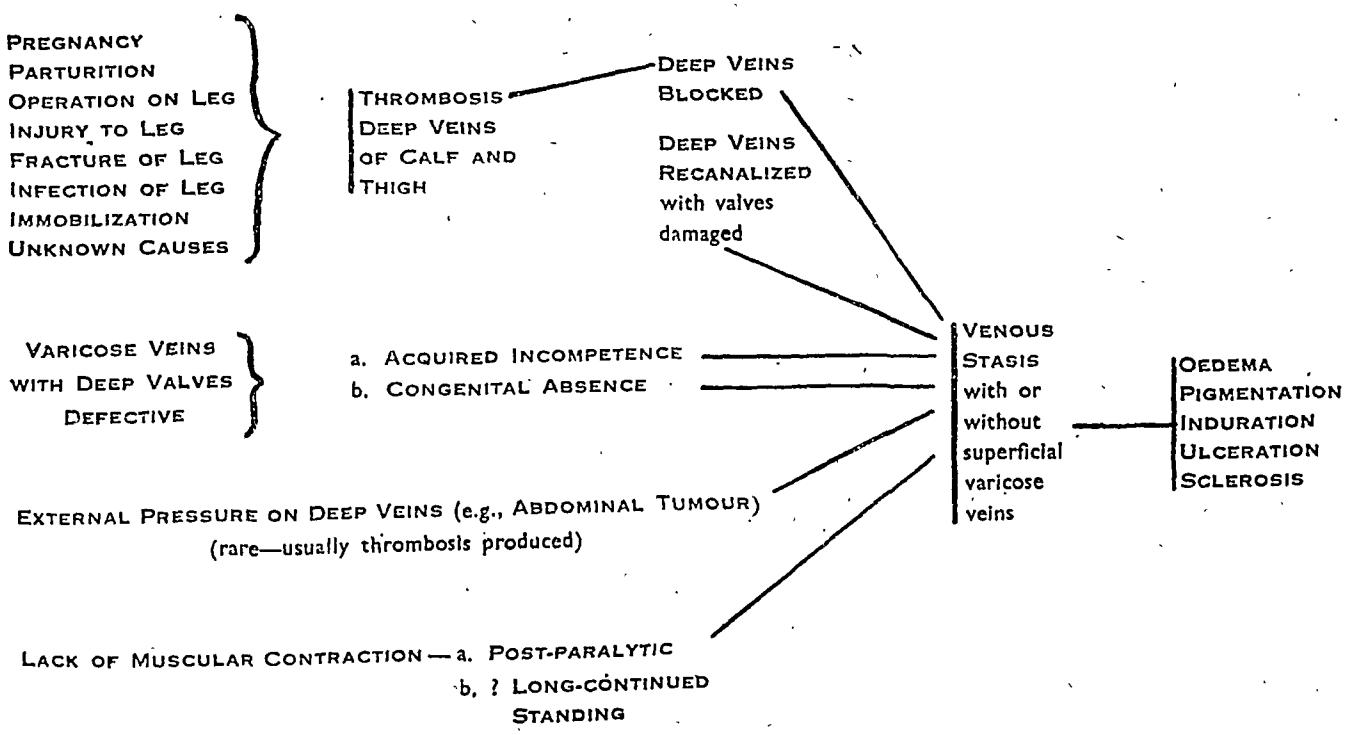

FIG. 2.—Causes of venous stasis in the lower limb.

2. Venous Stasis due to Miscellaneous Causes

A woman with congenital haemolytic icterus suffered from ulceration of the leg from the age of 17. Her mother and two sisters had ulcers of the legs.

A boot-repairer, whose mother had an ulcer of the leg, had suffered from acute anterior poliomyelitis as a child. His left leg was wasted and he wore a walking-calliper. A gravitational ulcer appeared when he was 26. No varicose veins were present and there was no history of thrombosis. The ulcer was probably due to venous stagnation caused by lack of muscular contraction in the leg.

Discussion

The causes of chronic venous stasis, and hence of gravitational ulceration of the leg, are summarized in Fig. 2.

Thrombosis of Deep Veins of the Lower Limb

This had been present in about 89% of patients in the series and seems to have been the most important cause of gravitational ulcer. The pathology of thrombosis will not be discussed here, as the subject has been fully reviewed by Allen, Barker, and Hines (1946), Zilliacus (1946), and Birger (1947). Causative factors may be slowing of the blood flow, alteration in the composition of the blood leading to an increased tendency to clot, and injury to the *intima of the vein. The blood flow in a leg vein may be* slowed by lack of muscular activity, by pressure on the vein from outside, and owing to defective venous valves. Thrombosis may take place with no apparent cause, as in 19 patients in this series.

Homans (1934) pointed out the importance of the deep veins of the calf as the site of origin of thrombosis in the lower limb. In two large series of cases of pulmonary embolism examined post mortem by Rössle (1937) and Neumann (1938) the calf or plantar veins were the site of thrombosis in the majority. This was confirmed by Putzer (1939), Frykholm (1940), Bauer (1941), and Hunter, Krygier, Kennedy, and Sneeden (1945). Only 10% of all thromboses in the femoral veins are not associated with deep thrombosis below the knee (Homans, 1943).

Thrombosis in the veins of the calf may cause pain and deep tenderness (Homans, 1934; Boyd, 1948), but often a "*silent thrombosis*" *has been demonstrated in patients with* pulmonary embolism (Homans, 1943) and by phlebographic examination (Bauer, 1941). The absence of any history of thrombosis in a patient with gravitational ulceration is therefore no evidence that the latter is not post-thrombotic in origin, and probably only by phlebography or dissection can the point be settled in a particular case. It is possible that some of the patients in the present series with no history of thrombosis had suffered from a "silent thrombosis."

Thrombosis originating in the lower part of the leg tends to extend centrally, often into the ilio-femoral vein. As a result of such thrombosis the venous return from the lower limb is impaired, as Gay (1868) observed, the lumen of the deep veins being occluded, though sometimes not

completely. Periphlebitis secondary to an aseptic inflammation of the wall of the veins (phlebitis) may be present (Bauer, 1948). Later, recanalization of the thrombosed vein may take place, but the valves are permanently destroyed (Homans, 1917; Edwards and Edwards, 1937; Bauer, 1948). This recanalization and valve destruction in the popliteal and femoral veins leads to marked venous stasis in the lower limb when the individual is erect. Linton and Hardy (1948) believe that ulceration of the leg does not take place until the thrombotic veins have become recanalized, and that this may take from one to 29 years from the time of venous thrombosis.

Varicose Veins

These may usefully be considered as primary or secondary. The primary type develops spontaneously and is probably due to inherited weakness in the structure of the vein—dilatation of the vein leading to incompetence of the valves (Edwards and Edwards, 1940)—or to congenital absence of valves as described by Eger and Casper (1943) and Curtis and Helms (1947). The secondary type develops as the result of thrombosis of deep veins in the lower limb (Meyer, 1932), though if the latter has been "silent" it may be difficult to distinguish this type from the primary. Post-thrombotic ulcers may be associated with such varicose veins of secondary type.

Do varicose veins of the primary type lead to venous stasis and ulceration? Varices may occur, as Meisen (1932) pointed out, with stasis and without stasis, and stasis may occur without varices (as in 31 patients in this series). The two may be independent. Clinical experience suggests that primary varicose veins, sometimes quite severe, occur not uncommonly without venous stasis. However, stasis and ulceration may be found with primary varicose veins, and the condition is well described by Bauer (1948). A family history of varicose veins is usual, a history of deep thrombosis is absent, women are affected twice as often as men, a bursting sensation is present in the legs on standing, oedema and other signs of chronic venous insufficiency are present similar to those following thrombosis, but phlebography and operative exploration differentiate the conditions. Bauer (1948) believes that idiopathic or non-thrombotic femoral incompetence, as he names it, is due to deficiency of the valves of the femoral and popliteal veins caused by phlebosclerosis affecting the deep veins, and not merely the superficial veins as in primary varicose veins, without evidence of venous insufficiency. Probably a similar result is produced by congenital absence of valves in the deep veins (Eger and Casper, 1943; Curtis and Helms, 1947).

Thus with primary varicose veins ulceration may be present if there is congenital or acquired absence or incompetence of valves of the deep veins. Ulceration may be absent if only the superficial veins are varicose. Thrombosis may occur, however, in the deep veins of patients with the latter condition, following treatment of the superficial varices, or may be due to any of the causes which lead to thrombosis in an individual without varicose veins. A post-thrombotic ulcer may result. In the present series primary varicose veins do not seem to have been a cause of ulceration in many patients, as only 32 (11%) gave no history of previous thrombosis. Three of these did not have primary varicose veins, and of the others some may have had a "silent" thrombosis.

Venous stasis due to complete absence of muscular contraction is rare, only one patient in the series having gravitational ulceration from this cause (previous anterior poliomyelitis), but comparative lack of movement while standing at work may be a secondary factor of note in some patients with ulcers.

Arterial Disease

Gay (1868) and Heller (1943) considered arterial disease to be an important cause of some chronic ulcers of the lower part of the leg. More recently Hines and Farber (1946) have described ulceration of the leg due to arteriosclerosis and ischaemia occurring in the presence of hypertensive disease, with no other vascular or cutaneous disease. Although in the present series no ulcer was thought to be due only to arterial or arteriolar disease, the high proportion of patients with hypertension suggests that this condition may be a factor in the aetiology of gravitational ulcers. Obliterative arterial disease may occur without a rise in blood pressure. The presence of an arterial factor in the causation of some ulcers may account for the beneficial effect of sympathectomy in certain patients (Borrie and Barling, 1948).

The treatment of chronic venous insufficiency and ulcers of the leg will not be discussed here, but it is clear that to be effective an accurate diagnosis of the cause and a knowledge of the aetiological factors involved are important.

Treatment

In this country at the present time the concentration on treatment of superficial varicose veins in patients with venous stasis is neither rational nor useful, and the results, as shown in several patients in this series, may be appalling. More often than not it is harmful, increasing the degree of stasis already present. Progress will be achieved only by a better understanding of the essential causes of the condition. Measures to prevent thrombosis are important, and when venous stasis has appeared the continued use of elastic supports to prevent oedema is essential. Various surgical techniques, such as those of Bauer (1948) and Linton and Hardy (1948), require consideration.

Summary

A series of 270 patients with gravitational ulcer has been investigated. This type of ulcer results from chronic venous stasis of the lower limb. In 88.6% venous stasis was due to previous thrombosis of deep veins in the leg. Varicose veins may be present as a result of thrombosis, but primary varicose veins rarely cause venous stasis and gravitational ulcer. The futility of treatment of the condition by attention to superficial varicose veins is stressed.

I am grateful to Dr. J. T. Ingram and Dr. F. F. Hellier for allowing me to carry out this investigation on their patients.

A NEW NEONATAL SYNDROME

BY

W. G. MILLS, F.R.C.S., M.R.C.O.G.

Assistant Obstetric Surgeon, United Birmingham Hospitals

During the ten-months period December, 1946, to October, 1947, a new syndrome affecting infants appeared in the nurseries of the Birmingham Maternity Hospital. Eight cases were observed, the predominant feature being a circulatory disturbance in one or both lower limbs, while some cases in addition showed muscular weakness or palsy. The case incidence was sporadic, and on only one occasion was the interval between cases less than three weeks. The aetiology was unknown, and neither the medical nor the nursing staff could recall similar cases. Search for guidance in standard textbooks proved fruitless, and it was concluded that the syndrome must have been caused by some new factor, such as a new line of treatment, that had never before operated.

Case Reports

Case 1.—On April 6, 1947, a 60-hours-old infant was found to have a flaccid paralysis of the right lower limb with apparently complete sensory loss below mid-thigh; the leg was pale and cold and no arterial pulsation could be detected. The appearance suggested an embolism of the common femoral artery, but the exact time of onset was uncertain. Next day the foot was still pale and cold, but the calf showed a mottled cyanosis and in a short time the whole limb became warm and flushed. Patches of local discoloration persisted on the front of the leg, the heel, and great toe, and desquamation was followed by scab formation and a chronic ulcer over the anterior border of the tibia. At 1 month old there was still a small unhealed ulcer, and considerable weakness in the anterior tibial group of muscles. At 2 years old there was a pes cavus, a limp, and poor dorsiflexion of the foot.

In an attempt to elucidate the aetiology the obstetric history was checked in detail. The mother, a primigravida, had been treated in hospital from the 34th to 38th week of pregnancy for pre-eclamptic toxaemia. Labour had been induced surgically, but after three days' inertia delivery had been effected by lower-segment caesarean section under general anaesthesia. The child was asphyxiated at birth, and was resuscitated with oxygen and an injection of nikethamide into the umbilical cord. It weighed 5 lb. 3 oz. (2.35 kg.). It had not been delivered through the incision by traction on one leg, and *no injection* was recorded as having been given into the buttock. The only conclusion that could be reached was that spontaneous thrombosis or embolism of unknown origin had occurred in the main artery to the limb.

It was then recalled by the ward sister that a somewhat similar though more severe case had occurred a few months previously, and that the child had subsequently died.

Case 2.—On consulting the records it appeared that a child had been delivered spontaneously on Dec. 14, 1946, following surgical induction of labour at 37 weeks for disproportion in a primigravida; the second stage of labour had been prolonged to three hours, and the child, weighing 6 lb. 9 oz. (2.98 kg.), had been born in a state of white asphyxia. Its condition being critical, nikethamide followed by lobeline and a second dose of nikethamide had been injected into the umbilical cord without any immediate effect. Six hours later the right leg was seen to be cyanosed and flaccid, with some oedema of the buttock, and during the next day it became cold and anaesthetic. Gangrene of the extremity developed and the infant died on the eleventh day from peritonitis. Necropsy showed thrombosis of the right common iliac artery and also of the inferior mesenteric vessels; there was gangrene and perforation of the sigmoid colon.

No common aetiological factor could be deduced from these two cases, although it seemed probable that the one was a more severe variant of the other. However, the next three months produced five more cases which, although not so severe, presented sufficient similarity to those preceding to warrant grouping together.

Case 3.—A child was delivered on April 30, 1947, by caesarean section for placenta praevia; a general anaesthetic was used. The child was sleepy and asphyxiated at birth, and three injections of nikethamide were given into the cord before respiration was established. On the second day the left buttock was found to be discoloured and indurated as though severely bruised; there was no concomitant paralysis, and the condition resolved in a few weeks without ulceration. It could easily have passed unrecorded had the previous cases not stimulated interest and observation.

Case 4.—This child was seen on May 25. Labour had been induced at 37 weeks in a primigravida with a posterior position of the occiput, but there was an interval of three days before the onset of labour. Intrauterine infection developed, and eventually a small infant 5 lb. 3 oz. (2.35 kg.) was delivered in a state of white asphyxia. Nikethamide was injected into the cord, and recovery was uneventful until the third day, when an area of discoloration was noticed on the right buttock. This area was indurated as though severely bruised, and the overlying skin became necrotic, to produce an unhealthy ulcer which healed with difficulty in about a month. There was never any demonstrable paralysis.

Two further cases were recorded within 24 hours of each other three weeks later.

Case 5.—A baby born on June 18 was the second child of a woman aged 47; during a difficult forceps extraction of a 9-lb. (4-kg.) infant there was considerable delay in delivery of the shoulders, and the child was born in white asphyxia. Two doses of nikethamide were injected into the umbilical cord. Twelve hours later there was extensive discoloration of the right buttock and right side of the scrotum, and during the next two days the gluteal skin broke down to form an ulcer, and a tense hydrocele developed. Movements of the right lower limb were greatly diminished, and there was temporary palsy of the anterior tibial group of muscles. The gluteal ulcer healed in a month, and leg and ankle movements gradually returned to normal.

Case 6.—The coincident case was less serious. Labour had been induced at 37 weeks for disproportion in a primigravida, and an infant weighing 7 lb. 3 oz. (3.26 kg.) was delivered with forceps for foetal distress; its condition was only fair, and one injection of nikethamide was given into the cord. Three

days later the typical indurated area of discoloration had appeared on the right buttock, and movements were diminished at the right ankle. There was no subsequent ulceration, and recovery was complete in 10 days.

Case 7.—This child was born on July 16. The infant was delivered precipitately through a rachitic flat pelvis after a long delay at the brim, and its condition was so poor that cerebral haemorrhage was presumed. Its life was twice despaired of, but after three separate injections of nikethamide into the cord respiration was more or less established. Six hours later the child was still cyanosed. There was discoloration of the legs: the left showed a mottled cyanosis of the buttock, thigh, and flank, while the right was pale, atonic, and inactive; there was also oedema of the left side of the scrotum. Within an hour the pallor of the right limb had been replaced by deep cyanosis, but the child died within 24 hours and no further changes were recorded. Necropsy revealed cerebral haemorrhage and atelectasis with no demonstrable thrombosis or embolism in the main arterial tree of either lower extremity.

Following this case a tentative diagnosis was propounded, and it was hoped that further cases might be avoided. However, the arrival of a new resident two months later was followed by the eighth and final case.

Case 8.—This child was born on Oct. 1, 1947. Caesarean section had been performed on account of some disproportion and inertia, and the child's condition was poor enough to require nikethamide for resuscitation. Within seven hours the left buttock was cyanosed and mottled, the left side of the scrotum was discoloured, and the left leg was pale and atonic (see Fig.). The leg regained full movement within a few days, but the gluteal skin broke down to produce an ulcer, which healed in a few weeks.

Case 8. The area of discoloration of gluteal and scrotal skin is limited almost exactly by the midline of the body. The marks on the lateral aspect of the right buttock have been produced by pressure from the napkin on which the infant was lying.

Discussion

To summarize these eight cases, we have a neonatal condition that has apparently not been previously recorded: it is probable that cases of little severity have escaped notice in the past, and in fact search in the hospital records has disclosed reference to one such case in 1945. The chief characteristics include the onset of vascular disturbances shortly after birth in one or both lower extremities, with a predilection for the gluteal region, and sometimes a flaccid paralysis of the limb. In one infant there was a fatal issue from cerebral haemorrhage; in another the inferior mesenteric vessels were affected and the child died from peritonitis: in a third there was residual paralysis of the anterior tibial group of muscles. All the remainder recovered fully.

After the occurrence of the seventh case a determined effort was made to establish a diagnosis, and various theories were put forward. The unilateral bruising of the buttock suggested thrombosis or embolism of the inferior gluteal artery, which in foetal life represents the main arterial axis of the lower extremity. It is the chief branch of the hypogastric, which continues as the umbilical artery; the external iliac artery is very much smaller. The inferior gluteal artery contributes the chief blood supply to the sciatic nerve. Embolism was considered improbable on account of the bilateral effect in Case 7 and the mesenteric lesion in Case 1. No cause could be adduced for a primary arterial thrombosis. Injection of vitamin K into the infant's buttock was disproved. The obstetric procedures were so diverse, including spontaneous, forceps, breech, and caesarean deliveries, that there seemed small chance of finding a common factor. However, it was observed that all infants had been born in a state of white asphyxia, and all had required at least one injection of nikethamide for resuscitation. Speculation was aroused upon the possibility of an intravenous injection being responsible for an arterial lesion, when it was suddenly realized that in all probability the injection had been given on occasion into an umbilical artery.

The resuscitation of the newborn is always an emergency procedure, and if it should follow operative delivery the obstetrician may still be engaged in the treatment of the mother. In consequence, the anaesthetist or a junior hospital resident may be instructed to inject "nikethamide into the cord," by which it is intended that 0.5 to 1 ml. of nikethamide shall be injected into the umbilical vein and milked down the cord to the umbilicus. Instead of the familiar engorged cord with a prominent distended vein and two smaller encircling arteries, there will probably be a practically avascular structure in which two dark vessels are dimly discernible. The operator, unfamiliar with the appearance of the cord in states of shock, and anxious to discharge his duty rapidly, may select a vessel and puncture it with difficulty; whichever he selects will be wrong, for the vein is empty, transparent, and practically invisible, and the injection will have been made into an artery

It is my belief that in the past this accident has been by no means uncommon, and that the production of a pathological lesion depends upon three factors. The volume of injected fluid and the vigorous nature of the "milking" process will determine how much nikethamide enters the foetal hypogastric arteries, while the height of the infant's systolic blood pressure will decide how far the retrograde injection advances before being swept peripherally in the arterial stream. The actual pathology might be an arterial spasm with ultimate thrombosis similar to the condition in the upper extremity following accidental intra-arterial injection of anaesthetic solutions. The occurrence of a bilateral case may be explained by the use of both umbilical arteries, while the massive effect in Case 1 followed a triple injection —enough to fill the common iliac artery and overflow into the aorta and inferior mesenteric. It is hardly surprising that the notes record "no immediate improvement."

It may be argued that the above hypothesis is mere conjecture supported by circumstantial evidence, and it must be admitted that proof is still lacking. An attempt has

been made to demonstrate the relevant arterial distribution by injecting methylene blue into the umbilical artery of a living anencephalic foetus, but without success. Experiments have been made elsewhere to reproduce the lesion in cats, but no positive result has been obtained. The difficulty of such experiments lies in the fact that the injection must be made against the full force of the neonatal blood pressure, and the fluid is thus unlikely to travel so far in a retrograde direction as it would when the subject was shocked or gravely asphyxiated. However, it is of some significance that after explanation of the danger of intra-arterial injection to the resident staff no further cases were recorded; and those who are uncomfortably aware of having themselves made such an injection testify to the extreme facility with which it may be made in moments of stress and shortage of sleep. There is no satisfactory explanation of the variable interval between injection and discovery of the lesion (6–60 hours), and an inexplicable fact is the sudden appearance of this series of cases in a hospital in which the use of nikethamide by injection into the umbilical cord has been an integral part of the routine for neonatal resuscitation for several years.

Summary

A new syndrome is described, comprising arterial lesions with occasional paralysis in the lower limb of the newborn.

Eight cases are recorded as having occurred in a period of 10 months at a busy maternity hospital.

The aetiology of the condition remains unproved. It is suspected that the lesions may be due to injection of drugs into an artery in the umbilical cord. The evidence in favour of this theory is discussed.

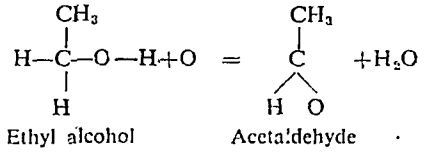
I am deeply indebted to Dr. Frances Braid for her interest in these babies and her stimulating encouragement. I wish to thank Dr. Hudson, of the Walton Hospital, Liverpool, for details of a similar series of cases, and the staff of the Birmingham Maternity Hospital, under whom the cases were admitted, for permission to publish.

A number of Government scholarships have hitherto been available to selected nurses who wished to train as nurse tutors. The assistance given has covered the training and examination fees and the cost of books, and provided an allowance of £150 for the period of training. The Ministry of Health has decided to end this arrangement and to substitute the following. Nurses, both male and female, who are accepted by training institutions for training as nurse tutors should be granted leave on full pay, including emoluments where appropriate, for the period of the training. The nurse would be required to pay the full cost of the training, including examination fees and books. The courses cover an academic year and begin in the latter part of September or early October. The recognized institutions which will be running courses next term are: Battersea Polytechnic, Battersea Park Road, London, S.W.11 (40 places); King's College of Household and Social Science, Campden Hill Road, London, W.8 (20 places); Royal College of Nursing, 1A, Henrietta Place, London, W.1 (36 places); University College, Hull (12 places). The fees for the courses vary from £20 to £50. Applicants must (*a*) be registered in the General Part of the State *Register*, or the Part of the *Register* for Male Nurses (General Trained); (*b*) have had at least three years' experience in nursing in hospital since registration in any Part of the *Register*, including at least one year as a ward sister (or corresponding rank in the case of a male nurse) in an approved training school; (*c*) satisfy the training institution that their general education is such as to justify taking up training. Where an applicant is registered both as a general trained nurse and as a mental nurse or nurse for mental defectives, but has not had a year's experience in charge of a ward, the applicant must have post-registration experience, satisfactory to the General Nursing Council, in an approved training school for a period of at least four years.

TETRAETHYLTHIURAMDISULPHIDE* IN THE TREATMENT OF ALCOHOLICS

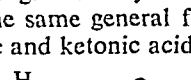
BY

A. E. CARVER, M.A., M.D., D.P.H., D.P.M.



Medical Director, Caldecote Hall

So numerous have been the drugs and techniques used and abused in the age-long struggle against alcoholic excess that one naturally is wary about recommending any new preparation. Yet tetraethylthiuramdisulphide, with the structural formula of $(C_2H_5)_2.N.C(=S).S.S.C(=S).N(C_2H_5)_2$, recently introduced by Dr. Erik Jacobsen, of Copenhagen, shows such promise that it merits extended trial so soon as it becomes readily available to the medical profession in this country. Adequate samples were placed at my disposal upon request, and the following preliminary report shows the advantages derivable from its administration.



The Drug's Action

Before relating these it will be of interest to expound the pharmacological basis of the drug's action. For many years it has been known that certain substances—e.g., cyanamide and the fungus *Coprinus atramentarius*—though innocuous to man when taken alone, yet gave rise to unpleasant symptoms when alcohol subsequently was consumed. Tetraethylthiuramdisulphide has a similar action, and the work of Dr. Jacobsen and his colleagues in Copenhagen has shown fairly conclusively that these characteristic effects are due to an interference with the normal metabolism of alcohol in the body, so that unusually high levels of acetaldehyde become present in the blood stream. Acetaldehyde is a normal intermediate stage in carbohydrate metabolism, and after alcohol its presence in the blood shows a temporary slight increase. When any member of the sensitizing group of substances now under discussion has been taken before the consumption of alcohol the blood acetaldehyde rises steeply (up to tenfold) and its elimination is slow.

Aldehydes are derived from the simple oxidation of primary alcohols, as is shown by the following equation with structural formulae:

Ethyl alcohol Acetaldehyde

Exactly how tetraethylthiuramdisulphide interferes with the normal metabolism of alcohol is not yet known, but there is an interesting correlation between this and the course of events in vitamin B_1 deficiency. In the latter case pyruvic acid, not acetaldehyde, is the stage at which metabolism goes wrong. Aldehydes and ketones are closely allied, having the same general formulae $C_nH_{2n}O$. Similarly the aldehydic and ketonic acids are closely related, and pyruvic acid,  , is the simplest of the ketonic acids. Later the relation between the mechanism of the two derangements in carbohydrate metabolism will probably be discovered. Possibly some similar if not identical inborn

*This drug has the proprietary names of "antabus," "antabuse," and "antalco."

error of metabolism will be found to account for the hypersensitivity of certain individuals to small doses of alcohol.

Tetraethylthiuramdisulphide has an advantage over other sensitizing drugs in that, though its action is prolonged, lasting several days, there is no evidence of cumulative toxic effects in the dosage usually employed. Moreover, it is easy to carry and to administer orally in tablet form. No symptoms arise unless and until alcohol also is ingested. Then typical symptoms begin with a burning sensation in the face. This is followed by injection of the conjunctival vessels and redness of the face. The loose tissue around the eyes becomes congested and the patient may have difficulty in keeping his eyes open. The pulse increases in frequency and may gradually rise to 150 a minute, but there is little if any change of blood pressure, though most patients complain of a pounding at the heart. Giddiness, hammering in the ears, and headache are next to appear, and the patient complains of a vague generalized anxiety and distress. Finally, if the doses of both substances have been large, he vomits and feels "thoroughly ill." Symptoms begin within a quarter of an hour of the intake of alcohol and last a variable time (up to five hours), then fade away gradually in sleep. On the following day the patient feels lackadaisical and listless, but is capable of carrying on his work.

These typical symptoms, of course, are subject to considerable individual variation in their march and severity, but the above recital affords a general picture of the average patient under close observation. Advantage has in two ways been taken of the disagreeable sequelae of this drug plus alcohol as an aid in the total treatment of excessive drinkers.

Method of Treatment

First, in a special institution for the rehabilitation of alcoholics those patients allowed out on parole receive a dose of 1 g. the previous day and 0.75 g. at breakfast on the morning of the day of *congé*. As a knowledge of the effects of the drug has not yet spread abroad patients do not know the consequences which a breaking of parole will entail. They think that the tablets received are merely vitamins, to which they are accustomed. Should a patient upon his return from an outing complain that queer things befell him his physician draws the obvious conclusion, but, instead of asking awkward questions, explains that the susceptibility of persons under treatment is such that any lapse to alcoholic beverages is likely to be fraught with not unmerited distress.

As patients and public become knowledgeable concerning the properties of these innocent-looking tablets this particular device will cease to have strategic value and the second method must be adopted.

This method is frankly to discuss with the patient the way in which tetraethylthiuramdisulphide can be used to contribute to a cure in his individual case. He is then free to decide whether to co-operate in the plan. Though there is no pretence that the drug of itself can rectify the defective personality structure of which alcoholism is a symptom, it can, by temporarily rendering the lure of alcohol easier to resist, gain a sober interval in which the process of reorientation can be begun. Possibly also, though this is at present not proved, a small daily dose in a patient of good will may establish a permanent distaste for alcohol. Even so, unless those underlying motivations which prompted the patient to excess be adjusted he cannot be regarded as cured. The largely unconscious urges which gained neurotic gratification via alcohol will, if this means of escape be denied to them by pharmacological force alone, break out in some other and possibly more objectionable form. This drug is therefore not recommended as a quack cure, but as a powerful addition to our already existing therapeutic armamentarium.

Before regular administration of tetraethylthiuramdisulphide is begun the patient should be put to a clinical test as follows. After sensitization has been established in the way about to be described, alcohol is administered to the patient according to his usual habit when drinking. His reactions then are carefully studied throughout. The detailed recital of a single typical but rather severe case will be more instructive than any attempt at statistics in illustrating the method adopted during a course of general and psychological treatment.

Illustrative Case

A married man aged 42, with no children, was first admitted in 1947. He was a Cambridge graduate and barrister-at-law, teetotaller until the age of 25, when he began drinking, which rapidly became excessive. His behaviour towards his wife became so brutal that he eventually consented to undergo institutional treatment. Under this he improved and gained considerable insight. He had, however, a suspicion, not altogether unfounded, that his wife meant to leave him when he got cured, and while he was undergoing treatment was only keeping in touch with him from a sense of her moral duty. He showed all the signs of an overcompensated inferiority complex with an overwhelming wish to be in the limelight and the "life and soul of every party."

On his return home renewed quarrels with his wife soon led to relapse. He thereupon left home and took up quarters in a public house at a port, where he drank heavily. While thus disporting himself he received a severe blow on the head in a drunken brawl. This necessitated trephining for removal of a blood clot. After discharge from hospital he went home and for a time refrained from alcohol. Then, without knowing why, he relapsed and kept drinking up to a bottle of gin a day and had superadded acute exacerbations associated with amnesia.

He insisted, however, that he had no real desire for alcohol but wanted to be cured of his uncontrollable habit. His history was already known in detail, as he had by request written an autobiography during his first admission, and this was brought up to date when he of his own wish returned for treatment early in 1949. The advantages derivable from tetraethylthiuramdisulphide were then explained to him, and he readily promised his whole-hearted co-operation. After a few days' rest, sedation, and detoxication a first test with the drug was performed to gauge his individual reactions. A dose of 0·75 g. was given one evening, and was repeated next morning. At 2.30 p.m. he was given a "double" gin (2 oz. (57 ml.) of 70 proof alcohol). Ten minutes later his face became hot and red. His conjunctivae were bloodshot and his lower eyelids puffy. His pulse went up from 68 to 120. Respiration also increased and he complained of a pounding at the heart and in the head. At 2.50 p.m. another double gin was given. Within a few minutes the patient's distress increased, his pulse rose to 130, and he felt so squeamish that he was sure any more gin would make him sick. These symptoms gradually subsided and he felt normal in just over two hours.

That night 1 g. of the drug was taken, and again at 10 a.m. the next day. At 3.45 p.m. he was given 2 oz. of gin. Symptoms as previously described came on more quickly than on the first occasion. A second 2 oz. of gin was given at 3.55 p.m. By 4 p.m. he felt extremely uncomfortable, with all symptoms increasing in severity. He next complained of seeing double and feeling generally ill and confused. At 4.05 p.m. a third 2 oz. of gin was given. (This order of drinking was the man's usual, and without the drug did not upset him, but led to more drinks.) After this third gin he became rapidly confused and felt desperately ill and anxious; pulse 150, respirations 36. Tingling followed by anaesthesia of the left hand developed and he could not move his left ring-finger and little finger. (These latter unusual symptoms probably are associated with his cranial operation.) At this point his face became instead of red, and he complained of feeling cold. At 4·2

he vomited and asked to be allowed to go to bed. He complained of "noises in his head as if an engine were pumping away outside." At 5 p.m. he became sleepy and refused a proffered cup of tea and a cigarette. At 5.40, 5.45, and 6 p.m. he again vomited and complained that the vomit tasted unusually acid. He also felt "icy cold" but otherwise better. At 8 p.m. he vomited for the last time, and thereafter slept fitfully through the night.

Next morning he "felt a bit washed out" and "uneasy in the stomach," but he worked in the garden for two hours, morning and afternoon, as usual. Three days later, according to a previous arrangement, he travelled home (a long journey with two changes and waits, involving a three-days absence) to attend a meeting of directors, before, during, and after which he used on former occasions to indulge freely in drink. On this occasion he was primed with tetraethylthiuramdisulphide, 0.75 g. night and morning over the period. He did not experience any disagreeable symptoms and did not have any inclination to drink. His institutional treatment will shortly be terminated. Then, as an added precaution when in the outer world, a daily dose of 0.25 g. will be prescribed for a month or two with a view to giving him an added sense of security, as it has done to others.

Comment

There is a hope that in milder cases, with the help of tetraethylthiuramdisulphide, the patient may receive enough help and understanding from his environment to dispense with specialized institutional treatment, or at any rate to shorten its duration. This, however, will require careful judgment, and remains for future experience to evaluate. At present one is justified in considering that tetraethylthiuramdisulphide seems likely to occupy a useful place in the treatment of alcoholics, and that it merits extensive but cautious investigation. The reactions of each individual patient under his usual drinking habit should be carefully tested the day after an initial sensitizing dose of the drug. Under out-patient conditions vigilance is required to see that a patient who has been placed on a small regular dose of the drug is not also managing to consume some alcoholic beverage. Should he do so the dose ought immediately to be quadrupled.

Summary and Conclusions

The use of tetraethylthiuramdisulphide is recommended as a useful ancillary, but not as a substitute for, general and psychological methods in the treatment of alcoholics.

The pharmacological action of the drug is discussed. It is innocuous to man unless followed by alcohol, but certain precautions in its administration are advocated.

Details in a severe case of alcoholic addiction are related in order to illustrate the symptoms and technique in treatment.

Among developments that Governor Dewey has recently announced will be carried out in the New York State mental hygiene programme (*New York Times*, July 20) is the establishment of a new relationship between voluntary hospitals and State mental hospitals; the former will provide preliminary treatment for patients before they become State charges. A second innovation that he described as "my own private brain child" is the creation of a new intern system in which 200 men yearly will serve for two years as interns in every State mental hospital, which would pay interns more than the voluntary hospitals do. "This is a system of which I vigorously disapprove," he said, "unless it is a public necessity, and I think this is a public necessity."

INCIDENCE OF PHYSICAL DISORDERS AMONG PSYCHIATRIC IN-PATIENTS

A STUDY OF 175 CASES

BY

H. E. S. MARSHALL, *M.C.*, M.A., M.B., B.Chir.

(From the Psychiatric Unit, St. George's Hospital)

During my period of duty as resident medical officer to the psychiatric unit I was so impressed by the number of patients needing attention for physical conditions that I reviewed the case records of all those admitted to the unit in 1948 in order to estimate the frequency of such conditions among the patients treated and the relevance of these to their psychiatric conditions.

Material Studied

During 1948 the unit had the use of 28 beds—22 for females and six for males, though, owing to redecorations, not all the former were continuously available. A total of 179 patients were admitted, of whom four did not stay long enough to allow of full examination and so are excluded from this series. The number of patients studied was 175, comprising 124 women and 51 men. All were in need of psychiatric attention, and no purely physical criterion entered into their selection.

The predominant features of the psychiatric conditions found were as follows: affective reactions, 108 (endogenous depression 51, reactive depression 35, anxiety states 16, cyclothymic reactions six); hysterical reactions, 22; schizophrenic reactions, 20; obsessional reactions, 16; organic reactions, five; hypochondriasis, neurasthenia, behaviour disorder, and drug addiction, one each.

Abnormal Physical Conditions

In no fewer than 77 patients (44%) some physical condition needing attention was found. As might be expected, the incidence was higher in those over 40 than in younger patients (61% against 35%).

In four patients serious physical disorders were first discovered during examination in the unit, their presence not having been previously suspected; these comprised one case each of pulmonary tuberculosis, bronchial carcinoma, glioma, and major epilepsy. In two other patients serious physical disorders, not related to the psychiatric condition, developed during their stay in hospital; these comprised one case each of cerebral thrombosis and thrombophlebitis.

In the accompanying tables the various physical conditions found are analysed according to their apparent relevance to the psychiatric conditions for which treatment was required.

TABLE I.—*Physical Conditions Contributing to the Onset of Psychological Illness*

	No. of Patients
Gynaecological conditions (menopause, 6; pregnancy, 4; eclampsia, abortion, sterilization, puberty, 1 each)	14
Disorders of central nervous system (epilepsy, 3; cerebral contusion, glioma, internal carotid aneurysm, poliomyelitis, encephalitis lethargica, 1 each)	8
Disorders of respiratory tract (influenza, maxillary sinusitis, asthma, pulmonary tuberculosis, bronchial carcinoma, 1 each)	5
Orthopaedic conditions (prolapsed intervertebral disk, 2; fracture of tibia, 1)	3
Disorders of vision (cataract, Leber's atrophy, 1 each)	2
Endocrine disorders (acromegaly, hypothyroidism, 1 each)	2
Arteriosclerosis	1
Chronic nephritis	1
Intestinal obstruction	1
Otosclerosis	1

TABLE II.—*Physical Disorders Resulting from Psychological Illness*

	No. of Patients
Lesions resulting from suicidal attempts (of which 4 occurred before admission)	6
Asthma	1
Collapse of lower lobe of left lung	1
Physical sequelae of anorexia nervosa	1
Stomal ulcers	1

TABLE III.—*Physical Conditions Not Apparently Related Aetiologically to Psychological Illness, but Requiring Attention*

	No. of Patients
Disorders of central nervous system (epilepsy, 2; frontal lobe injury, cerebral thrombosis, narcolepsy, migraine, ataxia of unknown cause, tremor of unknown cause, 1 each)	8
Disorders of alimentary tract (dental conditions, 6; stomal ulcers, 2)	8
Disorders of respiratory tract (pulmonary tuberculosis, 3; emphysema, maxillary sinusitis, tonsillitis, 1 each)	6
Gynaecological conditions (pregnancy, cervical polyp, cervical erosion, retroversion of uterus, pruritus vulvae, 1 each)	5
Disorders of veins (varicosity, 2; thrombosis, phlebitis, haemorrhoids, 1 each)	5
Endocrine disorders (thyroid adenoma, 2; diabetes mellitus, hypothyroidism, 1 each)	4
Orthopaedic conditions (cervical rib, scoliosis, pes cavus, 1 each)	3
Anaemias	3
Hernia	2
Skin conditions	2
Rheumatoid arthritis	1
Detached retina	1
Otitis media	1
Chronic mastitis	1

Laboratory Investigations.—The number of patients showing abnormal findings from laboratory and radiological investigations are as follows:

Electroencephalography	13	Cerebrospinal fluid	2
Serum cholesterol	5	Blood urea	2
Chest radiograph	4	Basal metabolic rate	2
Skull radiograph	4	Ventriculography	1
Fractional test meal	3	Bronchography	1
Blood counts	3	Electrocardiography	1
Blood sugar	3	Blood Wassermann or Kahn	1
Barium meal or enema	2		

Summary of Findings.—Out of the 175 patients, 77 (44%) presented some physical condition requiring attention. Of the 10 patients (6%) whose physical condition resulted from psychological illness, there were six in whom the physical lesion was consciously induced in a suicidal attempt. In the other four the physical condition found had a definite psychogenesis. In 39 patients (22%) the physical condition was considered to contribute to the development of the psychological illness. In 26 patients (15%) the physical and psychiatric conditions did not appear to be aetiologically related.

Discussion

The importance of the psychiatric aspect in many patients suffering from undoubted organic disease is now widely recognized, and is reflected in the development of the concept of psychosomatic medicine. This has perhaps led to less emphasis being laid on the physical factors in psychiatric syndromes, especially in those which are not obviously of organic type. The figures given above indicate the importance of this aspect of psychiatry. That this may be underestimated in general wards as well as in psychiatric wards is indicated in a study made by Comroe (1936). He followed up 100 patients who after admission to a medical clinic were diagnosed as suffering from neurosis, and found that 24% of them had definite organic disease within an average period of eight months, and that in most of them evidence of the organic disease was present during the original admission to the clinic.

The variety and gravity of physical disorders present among patients attending for psychiatric treatment are illustrated by the three case histories quoted below.

Case 1.—Man aged 72. A case of endogenous depression with a history of three depressive illnesses in the last 16 years. No physical symptoms, and no abnormal physical signs except glycosuria. A glucose-tolerance test indicated a moderately severe diabetic condition, the patient needing stabilization on insulin as well as electric convulsion therapy for the depressive condition.

Case 2.—Man aged 45. Referred for investigation of attacks of dizziness and fainting, which his doctor was satisfied "were not organic in the main," and a single epileptiform fit a few days previously. The doctor added that the patient had always had some worry—about his job or his mother's health or his own impotence. The left arm had been amputated many years ago following an accident. The clinical findings after admission were summed up thus: "A bad family background and a long history of gastric trouble, probably of emotional origin; evidence of an overconscientious obsessional driving personality. A history of disturbances of consciousness for seven to eight years; these have ranged from transient attacks lasting from a few seconds to a minute, in which he feels his actions are mechanical, to complete loss lasting as long as an hour and followed by vomiting. No physical signs, but sensory disturbances in a phantom left hand may have an organic basis. In the last nine months he has been lacking in libido, has become anxious and depressed, and feels that he is irritable and less efficient than before." After electroencephalography, skull radiographs, and ventriculography a diagnosis was made of glioma in the right frontoparietal region, and the patient was referred for deep *x*-ray therapy.

Case 3.—Man aged 29. Referred on account of three fugues during the previous 18 months. He complained of headaches and dimness of vision in the left eye, and was stated to have become apathetic and irritable since a subarachnoid haemorrhage eight years previously. Skull radiographs showed a shadow having the appearance of a large calcified aneurysm at the bifurcation of the left internal carotid artery. There were a few rales at the bases of both lungs but no other physical signs and no symptoms referable to his chest. The E.S.R. was 40 mm. in one hour. Radiographs of the chest showed extensive infiltration of both lungs with cavitation, and the sputum contained tubercle bacilli.

Full medical and surgical facilities are clearly necessary for the satisfactory treatment of such cases as these. The modern mental hospital is admittedly provided with such facilities, but there are many psychiatric patients for whom admission to a mental hospital is undesirable, particularly in view of popular prejudice and misinformation. Henderson and Gillespie (1944) state: "Recent experience has shown that with modern methods of treatment a considerable range of mental illness can be treated in the wards of a general hospital: but this is on the whole to be regarded as a provisional arrangement pending the establishment of specially constructed and equipped clinics within general hospitals." Treatment in such a unit is not merely a matter of investigation and transfer elsewhere, and the average duration of stay of a patient there is comparable to that in a general ward (Sands, 1948). At this time, when so much hospital planning is taking place, it may not be inappropriate to call attention to the need for such psychiatric units, as exemplified by the facts quoted in this paper.

Summary

The incidence of physical disorders among 175 patients admitted to a psychiatric unit is analysed. In 44% the physical condition required attention. In 22% a physical condition contributed to the psychological illness; in 6% a physical disorder resulted from the psychological illness; in 15% physical and psychiatric disorders occurred together but were not apparently related aetiologically.

The importance of full physical investigation of all psychiatric patients is emphasized. The need for properly equipped psychiatric units in general hospitals is stressed.

I am indebted to Dr. Desmond Curran and Sir Paul Mallinson for their help in the presentation of this paper and for permission to

quote from the records of patients under their charge, and to Dr. J. B. Randell, Dr. H. F. Osmond, and Dr. L. Ford for their help.

FAMILIAL PERIODIC PARALYSIS

REPORT OF A CASE

BY

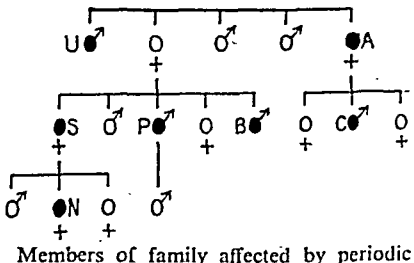
ERNEST SOYSA, O.B.E., M.B., M.R.C.P.Ed.
Major, Ceylon Medical Corps; Consultant Neuropsychiatrist, British Military Hospital, Colombo

Familial periodic paralysis presents a well-defined clinical picture. It was first described by Cavaré (1853), whose findings have been supplemented by studies of the electrocardiogram (Janota and Weber, 1928), of the electroencephalogram (Watson, 1946), and of rare features such as non-familial incidence, protracted seizures, visceral involvement, and fatal complications (Smith, 1939). Precipitation of attacks has been ascribed to physical exertion and mental strain, indulgence in carbohydrates or alcohol, alimentary disturbance such as overeating, hunger, diarrhoea, or constipation, and exposure to cold or damp. Postulated relationships between this and other conditions —e.g., endocrinopathy (Shinosaki, 1926), migraine (MacLachlan, 1932), muscular dystrophy (Biemond and Daniels, 1934), spinal vascular spasm (Vernon, 1936), chemical defect of the neuraxis (Pudenz, McIntosh, and McEachern, 1938)—are inconstant and indefinite.

The search for an adequate pathology was initiated by suspicion that muscular metabolism was deranged by some transitory autotoxaemia, which was suggested by arrest of gastric digestion and motility during the palsy (Mitchell, Flexner, and Edsall, 1902), and by transient urinary anomalies—e.g., acetonuria (Pastine, 1918), albuminuria (Shinosaki, 1926), and creatinuria (Ferrebee, Atchley, and Loeb, 1938). Recent studies of the blood chemistry of this syndrome have led to a fundamental advance in the state of knowledge as it existed between the review of the literature made by Singer and Goodbody (1901) and that by Schoenthal (1934).

From a casual observation that the potassium content of the blood serum was lowered during the palsy (Biemond and Daniels, 1934) there developed a new line of inquiry (Walker, 1935). A low serum potassium was found in attacks induced by administration of glucose in large quantities and insulin, separately and together (Aitken, Allott, Castleden, and Walker, 1937), and by adrenaline injection (Allott and McArdle, 1938). Attention has been drawn to alterations in the phosphorus balance of the blood (Milhorat, 1937; Allott and McArdle, 1938), variations in electrolyte features of the blood (Ferrebee *et al.*, 1938), and experimental evidence suggestive of a central controlling factor (Pudenz *et al.*, 1938). The pathogenesis of this disease presumably depends upon an excessive call for potassium in the muscles, its consequent withdrawal from the blood and retention in the body, with parallel changes in phosphorus metabolism. Undue lability of the serum potassium and phosphorus in relation to sugar mobilization perhaps conditions some motor dysfunction, such as interference with transmission of nerve impulses or inhibition of the muscular contractile response.

It has long been recognized that this palsy may be averted or arrested by the ingestion of various potassium salts—e.g., the acetate (Singer and Goodbody, 1901), the carbonate, the chlorate (Mitchell *et al.*, 1902), the bromide (Holtzapple, 1905), the chloride (Aitken *et al.*, 1937), the citrate (Herrington, 1937), and the phosphate (Allott and McArdle, 1938). The success of prophylactic potassium medication at night (Allott and McArdle, 1938) is probably related to nocturnal lowering of serum potassium in this malady (Gammon, Austin, Blithe, and Reid, 1939). Symptoms have been controlled also by choline esters (Pudenz *et al.*, 1938), pilocarpine (Guttmann, 1931), and pancreatic extract (Vernon, 1936), and averted by cod-liver oil (G.D.H., 1948).



The following case, which illustrates typical familial and clinical features of this rare and remarkable malady, shows a prominent association between muscular exertion and paralytic seizures, a striking hemiplegic distribution of symptoms, and a prompt response to potassium therapy.

Case Report

A South Indian male, aged 24, of a rice-eating race, serving in a labour corps in Ceylon, was referred for neuropsychiatric examination with a history of transient flaccid hemiplegic seizures occurring early in the morning after a hard day's work. A provisional diagnosis of hysteria had been suggested by the relation of these attacks to heavy work, their transitory duration, apparent response to bromides, irregular recurrence, and increasing frequency.

Personal History.—Symptoms had originated at the age of 17 with transient weakness of the lower limbs after strenuous work. As increasing frequency and severity of the disability began to interfere with his work as a cultivator, he had sought *ayurvedhic* treatment (herbals and massage), with apparent relief for several months. After resuming work, however, several relapses compelled him to abandon manual labour and obtain light work in a rural grocery store. This was followed by freedom from the disability. Enlistment in the Indian Army, six months before the time of examination, had been followed by another recurrence of symptoms, this time ranging in intensity from fleeting muscular weakness to profound loss of power lasting 2½ days. The frequency of attacks had increased from one in six to eight weeks to one in two to three weeks, having almost always affected both limbs of the right side, rarely having spread to the opposite side, and never to the trunk, neck, or head. The palsy evidently used to come on insidiously during sleep at night, as it would become apparent on awaking next morning without any premonitory warning. Spontaneous recovery had been the invariable termination of these seizures. Other past illnesses comprised two attacks of intermittent fever suggestive of malaria, and a few diarrhoeic episodes.

Family History.—Six other members of the patient's family, who were of coolie or labourer stock, had been afflicted by disabilities similar to his own, as indicated in the accompanying family tree. A maternal uncle, U, had suffered from occasional paralysis of his legs until his death, by accident, at the age of about 40. A maternal aunt, A, had had intermittent loss of power of her legs, but had gradually become free of her disability after about 25 years. This woman's son, C, was subject to paralytic attacks in his right arm and leg. The patient's elder sister, S, used to suffer from intermittent loss of power of her upper limbs, and one of her daughters, N, had a similar weakness of her legs. The patient's younger brother, B, had died in childhood during a para-

Members of family affected by periodic paralysis are shown in black.

lytic seizure of all four limbs and body. The patient, P, had been married for about three years. His only child had died of convulsions eight days after birth, but had exhibited no manifestations of paralysis. No information was available regarding the patient's maternal grandparents. No paralytic disability was known to have occurred in his father's family.

Investigations.—Observation in hospital for a fortnight revealed no physical abnormality; the urine, faeces, blood, and spinal fluid were normal. Psychiatric investigation disclosed no evidence of a psychogenic basis for the palsy.

As the classical features of familial periodic paralysis were recognizable in the history, attempts were made to induce symptoms. Four ounces (114 ml.) of glucose was given by mouth at 1 p.m. and again at 7 p.m. Weakness of the right arm and leg was reported the next day at 5 a.m., and of the left arm and leg at 6.15 a.m. By 10 a.m. all four limbs were in a state of flaccid paralysis with extinction of reflexes. Paralysis was profound on the right side, but weak movements of the left hand and foot indicated incomplete involvement of the distal muscles of the limbs on that side. Faradic reaction was abolished on the right side and feeble on the left. There was no motor disturbance of the trunk, neck, or head. The cranial nerves, abdominal reflexes, sphincter control, and sensory functions were normal. Urine was voided normally during the paralysis, but the bowel was not evacuated. Transient, mild glycosuria (0.02%), high acidity, and excess of urates were observed during the palsy. Results of systemic examination were otherwise negative. After a static period of about 26 hours, gradual return of power began distally and progressed to complete recovery in about 11 hours. Reflexes were restored later, but remained sluggish for about 18 hours, with coexistent aching and tenderness of the limbs. Four days later an attempt was made, without success, to provoke the palsy by subcutaneous injection of 10 min. (0.6 ml.) of adrenaline, repeated half-hourly from 9 a.m. to 3 p.m.

A spontaneous attack developed a week later, following exercise, the limbs of the right side only being affected. When paralysis was maximal 1 dr. (3.5 ml.) of potassium citrate in peppermint water was given by mouth. Symptoms passed off rapidly, with complete recovery in 3½ hours, leaving slight post-paralytic myalgia for about two hours.

As the patient's seizures were invariably nocturnal in incidence, a dose of ½ dr. (1.75 ml.) of potassium citrate was ordered as a routine prophylactic measure every night. No further recurrences were reported thereafter.

It was unfortunate that wartime conditions precluded biochemical study of this case—e.g., estimations of potassium, phosphorus, and sugar in the blood. I am not aware of a previous record of periodic paralysis affecting several members of an Indian family. The first such instance reported in a family in Britain is accredited to Farquhar Buzzard (1901). One of his three patients has recently described his symptoms, mentioning a persistent attack which had crippled him for three weeks (G. D. H., 1948).

I am grateful to Dr. C. Worster-Drought for his helpful comments and suggestions regarding this paper. He has kindly sent me an interesting note about one of three members of a family afflicted by this palsy who invariably develops attacks after bowling three or four overs at cricket, but never after batting or fielding. I am obliged to my colleague, Captain Oliver Medonza, for assistance in searching the literature available in Ceylon for references to this interesting syndrome.

Medical Memoranda

Some Presenting Symptoms of Carcinoma of the Bronchus

Carcinoma of the bronchus may give rise to a variety of presenting symptoms due either to the primary growth or to secondary deposits. The table shows the mode of presentation in 17 cases seen during a six months' appointment as house-physician at the Essex County Hospital. In these unselected cases from the medical and surgical wards of a general hospital nearly half presented with symptoms caused by metastases.

Presenting Symptoms	*No. of Cases*
(i) *Caused by Primary Growth*	
Cough, haemoptysis, blood-stained sputum, pain in chest, dysphagia, superior vena caval obstruction	9
(ii) *Caused by Primary Growth but simulating Pleuro-Pulmonary Infection* ..	
Fever and symptoms and signs suggestive of unresolved pneumonia or empyema.	2
(iii) *Caused by Secondary Growth*	
Paraplegia	3
Cerebral tumour	1
Pain in abdomen (ileum)	1
Gross enlargement of liver	1
Total	17

In cases in which carcinoma of the bronchus was diagnosed before secondary growth had caused symptoms death occurred within three months of the onset. Death supervened rapidly in this small series of cases, but some patients survive for two or three years after diagnosis. One case is worth recording in detail because of the unusual mode of presentation.

CASE REPORT

Up to six weeks before admission this woman, aged 39, had been perfectly well. Her first complaint was of swelling of the face and upper part of the trunk. She also had some shortness of breath at that time, but no other symptoms.

On admission, on Sept. 9, 1947, her most distressing symptom was a massive, painful enlargement of both breasts. They were enormous and intensely tender; pitting oedema and peau d'orange was manifest. The right breast was larger than the left, and while she was sitting in bed this breast rested on her thigh. There was no discharge from the nipple; no localized inflammatory or other mass could be detected.

She also had a severe persistent cough, with brown blood-stained sputum. Her temperature was 104° F. (40° C.), pulse 200, and respiration rate 48. She was pale, cyanosed, very dyspnoeic, and obviously moribund. There was oedema and puffiness of her face and both upper limbs. The neck veins were engorged on the right side, but not on the left. Enlarged tender lymphatic glands were palpable in both axillae and in

the right supraclavicular region. Examination of the chest showed consolidation of the whole of the right lung and a pleural effusion. The liver was grossly enlarged and tender.

The diagnosis in this case was not easy. There was obviously superior vena caval obstruction, and carcinoma of the bronchus with large hilar secondaries seemed a likely diagnosis. The gross enlargement of the breasts developing so rapidly and the shortness of the history were both confusing factors. Her condition rapidly deteriorated, and she died three days after admission.

Post-mortem examination confirmed the diagnosis of carcinoma of the bronchus with lymphatic obstruction and obstruction of the superior vena cava. There was a purulent tracheitis, bronchitis, and there were multiple small abscesses containing thick yellow pus in the right lung, which was solid with grey pneumonic consolidation. The right bronchus led into a firm white mass at the hilum of the lung.

This growth invaded the right lung deeply and occupied a considerable part of the mediastinum, being about 6 in. (15 cm.) in diameter. In the mediastinum the mass was a mixture of primary growth and secondary glands. The growth had penetrated through into the right auricle and superior vena cava, which was partially occluded. The left lung was congested; the right pleura contained a large yellow effusion. There was a toxic change in the myocardium and gross "bread-and-butter" pericarditis with dilatation of the neck veins.

On sectioning the breasts, the enlargement was seen to be due to oedema, which was also present in the presternal subcutaneous tissue.

I am grateful to Dr. S. A. Propert, Honorary Physician, Essex County Hospital, Colchester, for permission to publish this case, and to Dr. J. B. Penfold, who performed the post-mortem examination, for his advice and criticism.

J. PETER BUSH, M.B., D.R.C.O.G.,
Obstetrician, North Devon Infirmary, Barnstaple.

Pethidine as a Supplement to Nitrous Oxide Anaesthesia

The synthetic analgesic pethidine provides an alternative to morphine that possesses certain advantages over the natural alkaloid. The high degree of pain relief without respiratory depression or interference with the cough reflex, and the possession of certain atropine-like properties, have made it justly popular in obstetrics and in the relief of post-operative pain.

On a recent visit to San Francisco one of us saw this drug being administered intravenously as a supplement to nitrous oxide anaesthesia by Dr. William B. Neff, professor of anaesthetics at Stanford University, with excellent results both on the operating table and after. This use of pethidine does not seem to have been previously investigated in this country. We have since used it in upwards of 100 cases, with very gratifying results. It has been usual at the end of a long anaesthesia for the patient to reply to questions before leaving the table, and there has been a noticeable absence of post-operative pain and restlessness, often such a feature of other techniques where rapid recovery of consciousness occurs.

It has been our practice to put the patient to sleep with thiopentone and then administer nitrous oxide with some 30% of oxygen. An intravenous injection of 25 mg. of pethidine is given at the outset. This dose is repeated as often as is necessary to subdue any reflex activity on the part of the patient. We have found that 25 mg. of pethidine is needed about every 20–30 minutes in the average case. In abdominal and thoracic operations we have given occasional injections of "flaxedil" (a synthetic curarizing substance) or curare when the abdomen is tight or when the cough reflex is active. A rising pulse rate or blood pressure, or similar reaction to painful stimuli, is an indication that pethidine is required. The results during and after operation have been so good that we feel justified in publishing this early report, in case our colleagues may not be aware of the method.

We record our great debt to Dr. William B. Neff, who has developed this form of anaesthesia to a high degree.

Splint to Control Dorsal Subluxation of Proximal Interphalangeal Joints of Fingers

In the *British Medical Journal* of Dec. 11, 1948 (p. 1030), Dr. Trevor Howell stated that the problem of deformed fingers with ulnar deviation and subluxation was unsolved. In many of these cases the main deformity is a dorsal subluxation of the proximal interphalangeal joint, and in the Cowley Road Hospital, Oxford, we have introduced a splint which controls the subluxation while allowing free flexion of the finger. The splint is constructed of a single piece of heavy-gauge single-strand galvanized wire, padded and covered with leather. It consists of three transverse arms, one ventral to the proximal interphalangeal joint, and two others dorsal to the phalanges on either side of it. These arms are connected by side pieces, and the splint is so adjusted that the finger in maximum extension is slightly flexed, as in Fig. 1. As shown in Fig. 2, the splint forms

FIG. 1

FIG. 2

no bar to flexion to the limit of the capacity of the joint. The side pieces of the splint should be tight enough on the finger to maintain the splint in position during flexion.

The patients who have been provided with these splints have remarked on an increased range of usefulness of the hand. This is because the finger can no longer "lock" in a subluxated position, and also because the initiation of flexion is carried out with the finger in a much more advantageous mechanical position for the flexors, and therefore with more power. Further, if fixation of the joint is progressing, it will occur in a more satisfactory functional position if the deformity is controlled. None of the splints have been worn long enough to show whether their use can be curative, but it is possible that it might be so after constant wear for a period of several months. The splint is also useful in cases of this deformity arising from other causes.

(Since this note was written one patient suffering from paralysis agitans has undergone a complete cure of this deformity and now has a good functional hand after wearing the splint for nine months.)

My thanks are due to Dr. J. H. Spence, medical officer to the Cowley Road Hospital, for permission to publish this account, and to Mr. Eric Hillsdon for constructing all the splints since production of the prototype.

JOHN L. INSLEY, B.M., B.Ch., D.L.O.

Reviews

ABDOMINAL SURGERY

Abdominal Operations. By Rodney Maingot, F.R.C.S. Second edition. (Pp. 1,274; 468 illustrations. £4 4s.) London: H. K. Lewis and Co. 1948.

In the second edition of his book Mr. Maingot tells us that the considerable advances made in abdominal surgery during the last few years have forced him to revise the whole work thoroughly in order to bring it up to date. This revision is at once apparent, for the original two-volume book published in 1941 now consists of a single volume; and whereas the first edition was Mr. Maingot's own work throughout, with the exception of two chapters by two contributors who no longer appear, the present is the handiwork of eight new contributors in addition to the original author. The modernity of the book may be gathered from the fact that Chapter 16, by Lester Dragstedt, is on section of the vagi in the treatment of peptic ulcer. Certain omissions commented upon in reviews of the first edition have been made good; thus, there is an index of authors as well as of subjects. There is also a chapter by A. J. Cokkinis in which malrotation of the gut is discussed. In this section more reference might have been made to Norman Dott's notable paper on the subject. The historical notes which appear in various parts of the book, such as those in the chapters on subphrenic abscess, appendicitis, and diverticulitis, are excellent, many of them containing quotations from original papers.

In the diagram of various modifications of the Billroth II type of gastric resection (p. 223) I should like to have seen the Moynihan II no-loop, isoperistaltic anastomosis shown, as this has proved highly successful in the hands of many of his disciples and appears to be still popular. There are a few errors in the spelling of proper names—the appearance of Sir William's name as MacEwan (p. 820) may cause distress in Scotland, and that of Rodgers (p. 108) without the third letter lead to discontent in Northern Ireland.

There is an excellent chapter by Mr. R. C. Brock on post-operative chest complications and their management, but except for an article on local analgesia there is still no section on anaesthesia, an omission which was also commented upon in the review of the first edition. Perhaps the distinguished author prefers to leave the selection and administration of anaesthetics entirely to the anaesthetist, but the safety and ease of performance of abdominal surgery and the incidence of post-operative complications are so closely linked with the nature of the anaesthetic and its method of administration that a place might be found for general guidance in these matters in order to make this book complete.

This is a masterly work, the text of which is well arranged, clear, and eminently readable, while the illustrations are outstanding. Special notice should be given to them, since their importance in such a book, which is to be a guide to operating surgeons, cannot be overstated. They are for the most part the work of the Misses Larivière and McLarty and represent fine craftsmanship of which British surgical publishing may well be proud. The figures are clear and accurate as well as realistic, and should be a decided help to the young surgeon in the process of developing his technique or seeking guidance about an operation with which he is not very familiar. Some pathological material is well shown in both coloured and black-and-white plates by well-known medical illustrators such as Thornton Shiells, A. K. Maxwell, and others.

Among a series of textbooks on abdominal surgery Moynihan's two-volume book was outstanding up to the time of his death and for some years later. This is a work which in many respects resembles it, and bids fair to be a worthy successor and as valuable a guide to this generation as that of the great Leeds surgeon was to the generation before it. The author appears to have fully achieved his purpose of presenting a detailed consideration of the technique of modern abdominal operations.

LAMBERT ROGERS.

SURGERY OF THE STOMACH

The Surgery of the Stomach and Duodenum. By T. H. Somervell, M.A., M.B., B.Ch., F.R.C.S. (Pp. 546; illustrated. £2 5s.) London: Edward Arnold and Company.

Mr. T. H. Somervell, whose advocacy of "physiological gastrectomy" is well known, has here collected the results of his exceptionally wide experience of the whole range of gastric surgery. Although he is a complete convert to Hey's operation of vasoligation with, or occasionally without, an associated gastro-jejunostomy, his book is as unbiased an account of the surgical attack upon peptic ulceration as one could wish for; indeed, the description of his favourite method of treatment occupies but eleven pages of the book's total of over 500. His conclusions on this subject are well summed up in the preface: "It is not everyone who can perform an adequate gastrectomy with a low enough mortality to make it a justifiable operation. But many surgeons can do vagotomy, and all surgeons worthy of the name can devascularize the stomach with negligible mortality. All the evidence we have so far collected goes to show that the results of this operation are good." The chapter on vagotomy is written by Mr. Orr, who gives a well-balanced account of this innovation, including descriptions of both the transthoracic and the abdominal supradiaphragmatic operations.

The general outlook of the book is essentially balanced, and in controversial matters the author has been at great pains to present both sides of the question quite fairly; nevertheless, he usually has a definite opinion of his own. For instance, he is not in favour of the non-operative or expectant treatment of perforation except in the very gravest type of bad-risk patient, but he favours the Fowler position after operation provided all air is expelled from the peritoneum. He thinks that in very special circumstances there is a place for gastrectomy in the treatment of perforation. On the debatable question of the surgical treatment of bleeding from ulcers he is less definite, believing that the correct answer depends upon the capabilities of the individual surgeon: "For patients who are in the hands of an experienced surgeon I am in favour of early operation within 24 hours of the bleeding, backed by a transfusion controlled by intelligent observation." But how the surgeon is to assess his own capabilities cannot be told. He is enthusiastic on the transdiaphragmatic and transthoracic routes for access to the cardiac end of the stomach or oesophagus, and gives a good description of these operations. These are a few examples of the valuable conclusions and teaching to be found in these pages.

The book is well and copiously illustrated, the reproduction of radiographs and photomicrographs on the semi-art paper being particularly good. To sum up, this is a volume which can be highly recommended both to the novice and to the more experienced, for it is written modestly and with obvious sincerity.

NORMAN C. LAKE.

RADIOLOGY OF THE GUT

The Digestive Tract in Roentgenology. By Jacob Buckstein, M.D. (Pp. 889; 1,030 illustrations in 659 figures. £5.) Philadelphia and London: J. B. Lippincott Company.

The author's twenty-five years' association with Bellevue Hospital, New York, as a visiting radiologist, have provided him with a wealth of experience in gastro-enterological radiology.

The material presented in this book has been carefully and systematically selected. Each section is prefaced by a short anatomical description, a historical sketch, and a well-illustrated account of the normal appearances of the part under discussion. The method of examination of the part is described briefly in each major section. A short history of any case described is followed by the clinical, operative, pathological, and radiological findings. The radiological opinion is reserved to the end of the presentation. There is no air of infallibility, and where errors were made in the diagnosis the reasons are given without reserve.

Over a thousand illustrations of very fine quality are used, and they are properly keyed to the text so that the reader can follow them with the minimum of page turning. They really do show the points made, which is not true of all books on radiology. Each section has a satisfactory bibliography which is selected from publications in many languages.

Some of the author's statements are open to challenge. Many would not agree with him that "gastritis is a comparatively frequent disease," but they would share his caution in making the diagnosis radiologically. There is no doubt also that air in the duodenal cap is derived from that in the stomach, though the author would only presume so. In the discussion of short oesophagus the condition is considered solely as a congenital abnormality, and the possibility that shortening may occur later as a result of ulceration is not mentioned, even though a case fully described would seem to fit into the acquired category.

These are minor criticisms, and the book is strongly recommended in spite of its heavy cost: it provides a ready source of reference for the experienced radiologist and clinician, as well as being an excellent textbook for the junior radiologist or postgraduate trainee. The printing and paper are good and the bibliographic and general indices are clearly drawn up.

F. PYGOTT.

A SCHEME OF NEUROLOGY

A Textbook of Clinical Neurology. By J. M. Nielsen, M.D. Second edition. (Pp. 699. $7.50.) New York: Paul B. Hoeber, Inc.

Dr. Nielsen says in his preface to the first edition, "The book aims to present the subject of clinical neurology working from the simple to the complex . . . in so concise and clear-cut a manner and in sufficiently small volume that it may be used as a text of the subject during the time allotted to neurology in a general medical course." To this end he has systematically described the pathology and effects of diseases of each part of the nervous system, beginning at the periphery and finally reaching the hemispheres. He has then considered different forms of disease in turn; there are chapters on inflammations, tumours, and trauma, for example, and he has described entities such as the epilepsies, migraine, and intellectual defect in separate sections. Finally, he has an account of such special subjects as electro-encephalography, diseases of bones, and the vitamins. There are also two articles on neuroses and addiction which, though short, are much more useful than in comparable textbooks of neurology.

The presentation of neurology in this book follows the German method, with an emphasis on syndromes and proper names which is now unfamiliar in this country, and which many think undesirable. This is most clearly shown in the chapter on syndromes of the brain stem, which includes not only the Wallenberg syndrome, the Millard-Grubler syndrome, and the Foville's syndrome, but also Avellis's, Schmidt's, Jackson's, and many others. This form of presentation makes a demand upon memory which is beyond the capacity of some students and most neurologists.

The second edition has been brought up to date, particularly the sections on the treatment of infections. It is admirably produced and well illustrated.

DENIS WILLIAMS.

THE BASIS OF DISEASE

Biology of Disease. By Eli Moschcowitz, M.D. (Pp. 221. $4.50.) New York: Grune and Stratton. 1948.

In this collection of 24 essays, previously published in various journals, the author is concerned with the biological processes underlying a variety of clinical syndromes. He feels that too detailed classification of diseases is potentially dangerous, because thereby we may obscure the fact that similar derangements of function are common to several of them. Moreover, he believes that a number of chronic diseases are not separate entities, but represent the same morbid process at different stages of evolution. Thus he regards neuro-circulatory asthenia as the precursor state of Graves's disease, and cites examples where he has had patients under prolonged observation and has watched the transition.

The author displays an eclectic taste in his range of subjects. He discusses on the one hand common conditions such as arteriosclerosis, peptic ulcer, uraemia, Graves's disease, and obesity, and on the other uncommon illnesses such as periarteritis nodosa, Libman-Sachs disease, and follicular lymphoblastoma. Because of his preoccupation with the dynamics of disease rather than with the accompanying diverse morphological changes, however, he achieves unity—which is all the more surprising because the book appears at first sight to be a conglomeration of articles on unrelated subjects.

Dr. Moschcowitz writes with enthusiasm about psychosomatic medicine. As he points out, it is as old as Hippocrates in conception, but recent years have been fruitful in clarifying our understanding of this aspect of disease. Among psychosomatic disorders he defines a group of hyperkinetic diseases which includes essential hypertension, Graves's disease, peptic ulcer, and cardiospasm, in all of which he believes there is a primary exaggeration of function followed by marked anatomical changes. He observes five stages in their evolution: (1) the constitutional, (2) the exaggeration of function, (3) the lability of signs and symptoms, (4) the fixation of this exaggerated function, (5) somatic changes. Unfortunately he does not throw new light on why emotional stress has different effects on different people. He recognizes this important gap in our knowledge, and, though rejecting the Adlerian postulate of "organ inferiority," can only fall back on the all-embracing concept of "constitution" as an explanation.

Not all of us will agree with his opinions, but most of us will enjoy reading his book.

SIDNEY TRUELOVE.

REFLECTIONS ON GENERAL PRACTICE

Cum Notitia: Reminiscences of a General Medical Practitioner. By D. A. Alexander, M.B., Ch.B. (Pp. 395. 12s. 6d.) Bristol: John Wright and Sons. 1949.

An unusual book which left me sorry that no more information is given about the author than can be gathered from the text and the scanty note in the foreword. This introduction merely tells us that it is a collection of medical papers arranged as letters from a father who loved his profession to a son who felt unable to follow it, and that the author died suddenly before the book could be published. It is clear, however, that he was a happy man of wide reading and culture who was intensely interested in his patients. He was old-fashioned in some ways, but curious about new developments which might help him in his work and answer some of the questions about which he was always speculating. He tells us that an editor to whom he submitted a paper said, "You are a born speculator"—a verdict which all readers of this book will endorse.

It is a discursive work. The bulk of it is taken up by many careful and picturesque case histories. There are occasional, and too rare, reminiscences of colleagues and assistants, and a vivid account of his visit to the B.M.A. Annual Meeting at Cambridge in 1920. He had been anxious to meet Sir Clifford Allbutt, for whom he had great reverence, and like most of us who were present was disappointed with Sir Clifford's portrait that was presented to him at the meeting. "In it," he says, "I could not see all that we admired in the Regius Professor." I liked his defence of routine and mechanical work (p. 256).

I hope I have given the impression that this is a book to be dipped into and savoured. It is a worthy record of some aspects of an obviously good man who was a general practitioner far above the average.

ALFRED COX.

MARRIAGE GUIDANCE

Marriage Counselling. By David R. Mace, M.A., B.Sc., Ph.D. With foreword by the Right Hon. Henry Willink, *M.C.*, K.C. (Pp. 167. 8s.) London: J. and A. Churchill. 1948.

The reader of this excellent book need no longer complain he does not know what marriage guidance is or what it tries

to do. Dr. Mace sets out in clear and simple language all that an inquirer seeks to know.

The backbone of marriage guidance is the group of counsellors at the centres throughout the country, who work for the most part on a voluntary basis. These counsellors correspond to general practitioners in medicine, and their function is to sort out the cases, arrive at a diagnosis, and where necessary refer them to specialists (who may be medical, psychological, social, spiritual, or legal). Reference to medical specialists should be through the patients' own doctors. The success of marriage guidance depends on team work, since the causes of unsuccessful marriage are manifold; each case presents an individual problem, and no one counsellor can expect to be able to cope with all.

The work should comprise education for marriage, suitable for all young people over 16, preparation for marriage for engaged couples, and guidance and remedial treatment for those already married. In the past too much of the work has been with desperate cases where the situation has almost or quite passed beyond control. Even so, some measure of success has been achieved, though accurate statistical evidence cannot be obtained. It is hoped that in the future more preventive work may be possible as the public gains confidence in the efficacy of the centres. The help given must be competent, sympathetic, and confidential, and the counsellors must be most carefully selected. The methods used for selection are described. On the whole, married middle-aged people are the best, as they are most acceptable to both husband and wife, who must almost invariably be interviewed separately. The counsellors work for sessions of three hours not more than once a day, often only once a week. The general aims are emotional catharsis, elucidation and explanation, and mediation. With increasing experience less and less recourse to specialists is necessary.

While trying to keep an open and uncritical mind on all problems, there are certain ethical principles which are maintained. Extra-marital intercourse is condemned; contraceptives are permitted and in some cases encouraged. No decision about artificial insemination has yet been reached. Although every effort is made to seek a solution other than divorce, in some cases it is regretfully admitted to be unavoidable. No attempt is made to quote individual cases, but there is a general survey of the causes of marital disharmony.

There is no doubt that marriage guidance has come to stay: it now has Government support as a constructive effort to allay the social menace of the broken home with all its attendant evils, and this book should have a wide circulation in order that the public, who ought to be interested, may learn what it is all about.

R. G. GORDON.

Percival Bailey's *Intracranial Tumors* (second edition; pp. 478, 155 figures, 16 plates; $10.50 or £2 15s.; Springfield, Illinois: Charles C. Thomas; Oxford: Blackwell Scientific Publications, 1948) has been out of print too long, for it is a useful book of an unusual kind. It is written in an authoritative fashion by a man who knows very clearly what he thinks about the brain, its structure, its functions, and the nature and effect of the tumours that grow in it. It is essentially an American book showing little, except inferentially, of British influence on neurology and neurosurgery. The basic plan of the work is pathology, a good starting place and one that befits the author, whose part in the identification and classification of brain tumours is well known. The clinical effects of tumours in various situations are demonstrated by graphic descriptions, often transcripts of what patient and doctor said to one another. The only disadvantage of this is that tumours in the same situation do not produce stereotyped results, so that the inexperienced clinician who expects his patients to make the interesting replies that Dr. Bailey records may fail to recognize the site of the lesion in someone else. This is particularly true of frontal tumours, the typical effects of which are not only frequently absent but may be mimicked by tumours elsewhere. The book is well and plentifully illustrated; the diagrams are good, though some of the more ambitious pictures are not. But, even though it has faults, Dr. Bailey's book retains its place as highly important. It is a statement of his own views, an account of his thoughts on a subject to which he has made many contributions of the greatest interest and importance.

SATURDAY AUGUST 27 1949

THE LAST OF THE GREAT EUROPEANS

Men of science have often been prominent among the great amateurs of the arts. But it is now unusual for poets, painters, or musicians to be serious students of science. In this issue of the *Journal* we are privileged to publish an appreciation of Goethe, whose bicentenary is now being celebrated, from the pen of Sir Charles Sherrington. It is surely fitting that the doyen of British scientists, whose profound knowledge of European literature illuminates the whole of his paper, should pay tribute to a great poet who not only studied science seriously but contributed original observations of his own. Goethe's influence on scientific thought is no longer widespread, but regard for his genius among "a cultivated public our civilized world over" still remains as great as ever.

The German word *Heiterkeit* is untranslatable. Perhaps "cheerful serenity" is as close a rendering as we can contrive in English. Goethe was one of the few great men of the modern age who had a deep sense of tragedy and yet achieved *Heiterkeit*. It was by no means his constant mood, for he was one of the moodiest of men. He was also a man of strong passions. His moods would chase one another with extreme rapidity. His passions were deep-seated and endured until the end—he was 83 when he died. His mind combined to an extraordinary degree the perceptive and creative faculties. Even in the year of his death he was so full of ideas and projects that he felt as though all the world were still before him. Goethe's was a complete and perfectly integrated personality—integrated both in itself and with external Nature, or what we have come to regard as that, for to Goethe, as to the ancient Greeks, Nature was not external. Nature to him was everything. It was for this reason above all that he could not accept Christianity; the doctrine of the Fall, the rupture in Nature, and the ineradicable sinfulness of man were wholly alien to his spirit. He could not accept the mediaeval view as expressed by Chaucer in the line:

> Nature, the vicaire of th' almyghty lorde.

For Goethe, God and Nature were one—complete and perfect. There would be something gruesome in his poem on the skull of his friend Schiller as it lay in the charnel-house, some inappropriate recollection of Hamlet musing over the skull of Yorick, were it not for the grandiose conception which makes the skull the temple of genius (an ancient temple, as it were, that once housed a divine spirit) and for Goethe's deep awareness that the skull is itself a noble structure and organic form. The poem, one of Goethe's greatest, ends with the marvellous—but untranslatable—lines:

> Was kann ein Mensch im Leben mehr gewinnen,
> Als dass sich Gott-Natur ihm offenbare?

All the emphasis lies upon *Gott-Natur*—God-Nature—the organic principle, the essence of all that Goethe believed in, lived and worked for, his religion and his philosophy in one. For theology he cared little, and for systematic philosophy even less, though he deeply revered Spinoza. That God-Nature should reveal itself to a man as it did to Schiller—this is the greatest happiness in life, the only enduring gain, the only fulfilment. Such is the meaning of these two lines which only a great poet could transmute into another language.

Goethe was a man who suffered much, and his "cheerful serenity" was but the aspect—though the inner as well as the outer aspect—of anguish and passion mastered and yet not forgotten. What was most astonishing about him was the immense power of intellect and imagination which enabled him to harmonize all contraries and discords in himself, in history, and in the world of his day. Although one of the deepest of writers, he was one of the least paradoxical. His conception of classical antiquity is out of date from an archaeological point of view, for modern research has disclosed what might be called the ancient underworld—the dark and daemonic forces in Greek religion, and the pessimism of the Greeks to which the great Burckhardt first called attention. Goethe saw "cheerful serenity" above all in the Greeks. And surely it is there; but much is there also of which Goethe had no knowledge. His judgment of Greek sculpture, known to him almost entirely through inferior examples of the late decline, is not our judgment. But even when he was mistaken he was profound and illuminating. We cannot simply discard his perception of classical antiquity. That perception did not merely record certain data—Goethe was little interested in data. Nor was it an *apparatus criticus*. It was a way of looking at things in their totality.

Although, as Sir Charles Sherrington points out, most of Goethe's work as a scientist has been superseded, it has extraordinary merits. Even when it is entirely mistaken it is interesting—and always readable. His work on the nature of colour has a value which made Turner, the greatest of English colourists, treasure it all his life. Goethe as a scientist did not seek for proofs, but propounded organic conceptions. He had an extraordinary sense of significant form.

Goethe despised politics, and yet few writings are as replete with political wisdom as his. The Germans were not yet a nation in his day. He warned them against trying to become a nation, and he told them: Do not on any account try to imitate Napoleon. The French Revolution was repugnant to him, but he had the gift of observing political phenomena *sine ira et studio* and yet with deep understanding, just as he would observe natural phenomena. He admitted that the French Revolution produced a revolution in himself, but the harmony of his own nature prevailed. He hated presumptuous ignorance. "There is nothing," he said, "more terrible than ignorance in action."

Classical antiquity, the Renaissance, and the modern world came together in Goethe. This is evident, above all, in his supreme masterpiece, the second part of *Faust*. Every character in this gigantic architectural poem is a type, every scene is symbolical, every event is significant. The poem contains the most grandiose scene of classical beauty in modern literature—the *klassische Walpurgisnacht*. It has the audacity and the sensuous splendour of the Renaissance and the perplexity, the sense of crisis, that mark our own time. He finished this work just before he died, fully aware that it would not be understood by his contemporaries. Only in our own generation has understanding come.

The period that immediately followed Goethe's was a period of prophetic genius—of Kierkegaard, Dostoevski, and Nietzsche. These great men were Europeans too, though Dostoevski would have disclaimed that title, but they belonged to the Europe that was already breaking apart. They not only stood on the verge of the abyss: they were already of the abyss. Goethe saw the abyss, but he was never of it. He was a prophet, but prophecy was not his vocation. His vocation was not to warn but to fulfil, not to paint the future or recall the past but to contemplate and reveal in symbolical terms—through the medium of poetry, drama, fiction, and science—the living, organic whole which, while it is always changing, is always the same. He would have rejected the evolutionary hypothesis, for to him Nature was complete and perfect, and every change was but a change from one perfection to another. He was a great moralist. He regarded evil as something against Nature, because Nature was not the realm of free and arbitrary impulse but the realm of form, structure, harmony, and law.

His genius was the last embodiment of that organic unity which the modern world has lost. He was the last of the great Europeans. The relevance of his warnings grows with every year. His influence upon his own generation and those that followed was pervasive—a kind of creative radiation, not an impact. He formulated no doctrine that moved the masses. Not one of his ideas stands alone. All his ideas—and they were many and varied—belong organically to one living conception. That the bicentenary of his birth should be celebrated throughout Europe and wherever European civilization has spread is evidence that Europe is not lost.

AN ANTIBIOTIC OF WIDE RANGE

We have referred on several recent occasions to reports from the U.S.A. on the therapeutic properties of "aureomycin."[1] Earlier accounts of this new antibiotic were not encouraging: indeed, its properties as demonstrable *in vitro* are such that an entire absence of therapeutic effect would not have been surprising. It is exceedingly unstable in ordinary culture media, so much so that the method of assay recommended is one in which the results can be read after only four hours' incubation. It is much less active in neutral or alkaline than in acid media, and serum diminishes its activity. That these unpromising characters are for some reason quite unrepresentative of the behaviour of aureomycin in the body is clear from the growing volume of clinical reports on its efficacy in a wide variety of infections. It has in fact a greater range of therapeutic activity than any other antibiotic, and its popularity in the U.S.A., where it is now being used on an enormous scale, is much enhanced by the ease of its administration. It is taken by mouth, and, although sometimes producing nausea, vomiting, and diarrhoea, is apparently free from any risk of more serious toxic effects.

With its action in rickettsial infections we in this country are fortunately not directly concerned, but the fact that there is now an effective treatment for typhus and similar diseases is a therapeutic advance of the first importance: in this the honours are shared between aureomycin and chloramphenicol ("chloromycetin"). Aureomycin has also an action on several viruses, including those of lymphogranuloma venereum and of primary atypical pneumonia. The latter disease was the subject of a very careful study by Meiklejohn and Shragg,[2] who laid down strict criteria in selecting their patients, whose disease was of rather more than ordinary severity. They also treated an exactly comparable control group with penicillin. Although about half the control group recovered fairly rapidly, a prompt therapeutic response was invariable in those treated with aureomycin. A few patients relapsed, but they responded rapidly to further treatment. It is a remarkable fact that aureomycin is a specific for every common form of

[10] *Proc. Mayo Clin.*, 1949, 24, 309.

pneumonia, whether due to a bacterium or a virus. Among highly susceptible bacteria are the pneumococcus and other Gram-positive cocci, and *H. influenzae* and certain other Gram-negative bacilli: susceptible viruses are those of primary atypical pneumonia and of psittacosis. It is perhaps unnecessary to point out that the demand for a drug which can justifiably be given on making the clinical diagnosis of pneumonia, without waiting for, or even undertaking, a bacteriological diagnosis, is likely to be considerable.

To pneumonia in general can be added venereal disease in general, as was pointed out recently in this *Journal* by Drs. R. R. Willcox and G. M. Findlay.[3] Lymphogranuloma venereum and granuloma inguinale have both been found to respond, as also have syphilis, gonorrhoea, and, in the experience of the authors quoted, non-specific urethritis associated with the presence of pleuropneumonia-like organisms. It should be understood that the action of aureomycin on gonorrhoea is inferior to that of penicillin, and only likely to be exploited should penicillin-resistant strains of gonococci appear, and that its effects in syphilis require much further study. Information about the latter is confined to a few reports from the Mayo Clinic, in the latest of which O'Leary and his colleagues[4] describe the rapid healing of lesions of late cutaneous syphilis, and the early stages of a study of the treatment of neurosyphilis. It should be remembered that Heilman[5] has already shown experimentally that aureomycin is more effective weight for weight than penicillin in the treatment of relapsing fever and leptospirosis: thus evidence of activity against "spirochaetes" is accumulating.

Aureomycin is now acknowledged to be much inferior to chloramphenicol for the treatment of salmonella infections, including typhoid fever. On the other hand, the evidence is now conclusive that it has a remarkable effect in brucellosis. Spink and his colleagues[6] are among those who have gone to Mexico to exploit the abundance of clinical material of this kind to be found there, and they report enthusiastically on the treatment of 24 patients with bacteriologically proved *Br. melitensis* infections, some being of great severity. Debono[7] also has reported from Malta that the immediate response to treatment was excellent in 24 patients infected with *Br. melitensis*. The successful treatment of a patient with a *Br. abortus* infection was described recently in this *Journal* by Galpine.[8] Among other bacterial infections, nothing conclusive about the action of aureomycin in tuberculosis has yet been reported, though a single observation by Schoenbach and his colleagues[9] suggests that there is such an action. On the other hand, it is already quite clear that a wide field of essential use for aureomycin exists among penicillin-resistant infections due to staphylococci. The increasing prevalence of these organisms has caused much disquiet, and is amply confirmed by Nichols and Needham,[10] of the Mayo Clinic, who found that of 50 recently isolated strains 34 were resistant to penicillin and 14 to streptomycin, but all were sensitive to aureomycin. In the last 15 cases of staphylococcal bacteriaemia treated at the Mayo Clinic the organisms from 12 were penicillin-resistant and from three streptomycin-resistant: all were inhibited by 0.78 μg. per ml. of aureomycin. Six of these patients were actually treated with aureomycin, with successful results in four.

There are so far few references in the American literature to the use of aureomycin in this type of case, but it is now a common practice, and aureomycin rather than streptomycin is generally regarded as the second line of defence when penicillin fails against staphylococci. Indeed, some authorities even go so far as to say that aureomycin should be given in addition to penicillin from the outset in a severe case, pending determination of the penicillin sensitivity of the organism. It remains to be added that, since aureomycin is active against all organisms commonly causing urinary tract infections except *Proteus* and *Ps. pyocyanea*, it is now very widely used in the U.S.A. as a urinary antiseptic, sometimes even before other drugs have been tried. Some of these uses are non-essential, and others, notably the treatment of rickettsial infections, do not concern us in Great Britain. But there remain three diseases in which aureomycin may sometimes be the only means of saving life. The task of those who have to decide how many precious dollars to spend on this new antibiotic and how to distribute such supplies as reach this country can be no easy one.

STREPTOMYCIN IN INFANTILE GASTRO-ENTERITIS

The rational use of chemotherapeutic drugs in infective gastro-enteritis of infants is made difficult by the many varieties of organisms to which aetiological significance has been attributed. A careful bacteriological investigation by Taylor, Powell, and Wright[1] was published in a recent issue of this *Journal*. The wide range of action of streptomycin, especially against Gram-negative bacteria, made it an obvious choice for clinical trial in this disease. Preliminary results indicate that even when no pathogenic organisms are isolated from the stools streptomycin may be effective, and among the earlier reports those of Leisti,[2] who treated 46 infants, all with negative stool cultures, and of James and his colleagues,[3] who isolated *Proteus vulgaris* from most of their cases, are favourable. The latter authors found that oral streptomycin alone was effective whether or not other foci of infection were present, and that even critically ill children were ready for discharge from hospital in from 9 to 12 days. However,

[1] *British Medical Journal*, 1949, 2, 117. See also leading article, p. 141.

[3] *Lancet*, 1948, 2, 555.

the conclusions of Drs. A. Holzel, G. Martyn, and L. Apter and of R. Debré and P. Mozziconacci in the papers published elsewhere in this issue show that much has yet to be learned.

The former conclude that streptomycin had no specific effect in cases which they studied. Seventy-nine infants were divided into three groups: the first, consisting of 26 cases, was given oral streptomycin; the second (24 cases) received intramuscular streptomycin; and the control group of 29 cases was not given chemotherapeutic treatment. The numbers of deaths in the three groups were 5, 6, and 3 respectively. The presence or absence of parenteral infection made no difference to the outcome. In 63% of the cases a type of *Bact. coli* var. *neapolitanum* was isolated from the faeces, but the authors do not consider that their findings indicate that this organism was necessarily the cause of the infection. The failure of streptomycin treatment in some cases may be attributed either to development of resistance by this organism or to cross-infection with a resistant strain. Although great improvement occurred in some infants, in others the drug had no effect, and the indications for antibiotic therapy in this condition remain obscure.

In the series of 41 cases of septicaemia and meningitis in infants reported by Debré and Mozziconacci the infection was due to intestinal organisms—members of the *Bact. coli* and *Salmonella* groups, *Ps. pyocyanea*, or other Gram-positive organisms. Signs of gastro-enteritis were an important clinical feature in all these cases. Streptomycin was administered intramuscularly and, where appropriate, by the intrathecal or intraventricular routes. Some of the patients received sulphonamide in addition. Twelve out of 16 cases of septicaemia without meningitis recovered, but only four recovered out of 25 cases in which meningitis was a complication. Again, many of the failures might be attributed to resistance of the organism. Strains obtained from blood or cerebrospinal fluid were sometimes sensitive to between 150 and 200 μg. per millilitre—concentrations which are not usually attainable clinically—but the authors were unable to find any relation between resistance and clinical progress, and they emphasize the importance of lesions which interfere with the diffusion of the antibiotic. Evidently the recovery of a streptomycin-sensitive organism from a case of infantile gastro-enteritis is not a reliable indication for streptomycin therapy. There are other, as yet unknown, factors which are important, and until these are elucidated treatment must remain largely empirical.

MEDICAL PROBLEMS IN WESTERN GERMANY

The medical problems of Western Germany are those of the whole of Western Europe writ large but with some special distinguishing features. A great increase in the population followed the exodus from Eastern Europe, and many doctors are among those who have had to leave their homes; some of these are still in displaced-person camps. Medical posts have yet to be found for doctors who were in the Services, or who have returned from prisoner-of-war camps in Russia, or who have fled from intolerable political conditions. Inevitably in a period of readjustment such as the present there are occasional complaints, mostly, it would seem, unfounded, that appointments have been made less on professional than on political grounds. All the medical schools are overcrowded with students and young doctors: a professor of medicine, for instance, will have at least a dozen paid assistants, in addition to a number of voluntary workers. Bomb damage has reduced the numbers of hospital beds, which would in any case have been insufficient to meet the needs of the increased population. In the now disused S.S. barracks, however, space has been found for additional hospitals, and many of these grim buildings have been skilfully converted into hospitals with self-contained cubicles for the nursing of patients with infectious diseases. Outside in the corridors are still the racks for stacking rifles. The bomb-proof underground bunkers constructed in many hospitals are still in use, in some cases as neurosurgical clinics where patients with brain lesions can be given complete quiet and rest. Bed linen at first was scarce, but now, after the devaluation of the mark in June, 1948, everything has become more plentiful. Penicillin is at last being produced on a commercial scale. Streptomycin too is available, and in one children's clinic it was claimed that 36 out of 71 cases of tuberculous meningitis had survived.

Many medical journals before 1939 were printed in what is now the Eastern Zone; arrangements have been made for publishing many of these journals in Western Germany, or, if this has been impossible, a new journal has arisen in place of the old. The *Archiv für Schiffs- u. Tropenhygiene*, for instance, exists no longer, but to replace it there now appears a new *Acta Tropica*. New medical books are also being published embodying the experiences gained during the war. One important work on hunger oedema gives many interesting facts which will be new to medical men in this country. Incidentally, children now seem to be well nourished and full of energy, and, apart from returned prisoners of war, the only signs of malnutrition still visible are in elderly men and women. Despite the difficult conditions under which most German doctors are working, there is a feeling of optimism and an intense desire to learn what has been going on abroad. The medical scholarships provided by the British Council are being eagerly sought. Medical research has never entirely ceased in Germany. Ultracentrifuges and electron microscopes are being produced, and new and remarkable apparatus has been devised for subjecting bacteria and viruses to ultrasonic vibrations.

Apart from outbreaks of diphtheria and paratyphoid B and some increase in indigenous cases of malaria, there has been no serious epidemic in Western Germany, though in 1947 poliomyelitis was more prevalent than for many years. Venereal disease, especially syphilis, increased alarmingly immediately after the end of the fighting, but the incidence is now decreasing.

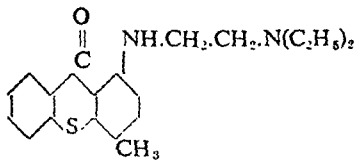
Last year the Foreign Office published a report[1] prepared by the Medical Research Council entitled "Tuberculosis in the British Zone in Germany." While the 1946–7 figures showed no general fall in the tuberculosis mortality, there were no signs of any alarming increase. In Hamburg, for

[1] See *British Medical Journal*, 1948, 1, 503.

instance, the death rate from pulmonary tuberculosis during the post-war period has declined. It is believed, also, that the numbers of cases of coronary thrombosis and diabetes have not increased. There is much interest in the British National Health Service, especially among those engaged in medical administration, who feel that as soon as a German Government is established an analogous scheme will have to be set up in Germany.

GRAVITATIONAL ULCERS

No doubt the erect posture is responsible for certain weaknesses in the legs of man. The location of many lesions in the leg—for instance, chilblains, erythema nodosum, and the gummatous phases of tuberculosis and syphilis—is determined to a great extent by circulatory and gravitational factors. The necrobiotic, myxoedemic, and other expressions of metabolic disturbance, and the eruptions and ulcerations which may accompany anaemia, deficiency states, and acholuric jaundice, are indications that the aetiology of diseases affecting the legs is not necessarily straightforward. Such factors should not be overlooked when considering the so-called varicose or gravitational ulcers which cause so much serious disability in the community. The condition is not limited to any one section of the community, but the incidence is greatest among those least able to rest and support their limbs—the essentials of treatment.



The influence of age, sex, occupation, and heredity is important, and work which entails standing with little activity may be a serious aggravation. Hypertension or arterial disease sometimes plays a part. It should be emphasized that the treatment of gravitational ulcers of the legs is an individual problem: there is no satisfactory rule-of-thumb procedure. Too much attention has been paid to the presence of superficial varicose veins. In a review of the subject in this issue of the *Journal* Dr. S. T. Anning suggests that treatment of such veins is often useless and may indeed be harmful. The value of compression and support—both still of the utmost importance—in expressing stagnant fluids was stressed as long ago as 1676 by Richard Wiseman and again in 1783 by Michael Underwood.[1] "Put the hydraulics right, and the ulcer will take care of itself" was a phrase used by Dickson Wright,[2] whose advocacy of these measures, including the use of elastic adhesive bandages for support, has not had the wide support in general practice which it deserves.

Dr. Anning finds that in the majority of patients (88.6%) the venous insufficiency affects all the tissues of the limb and is a result of thrombosis of the deep veins. This may be followed by recanalization, but as a result of damage to the valves in these veins and in the vessels communicating with the superficial veins there is grave functional incompetence, stasis of lymph and blood, and oedema and consequent devitalization of tissue. Phlebography may indicate much of this and should be undertaken before interfering with any superficial varices. In this condition the ulcer is a complication, not the essential abnormality. There is some place for methods of treatment which assist the ulcers to heal, but most emphasis should be on prevention. Whatever use is made of temporary expedients; effective support of the limb to counter the venous insufficiency and stasis should be an essential part of the permanent routine—for life in most cases. The many books and papers on this subject in the last 20 years have not been very fruitful. Dr. Anning's observations may help to direct attention from the floor of the ulcer and from the superficial veins to the underlying condition.

THE MIRACILS AND SCHISTOSOMIASIS

Until the second decade of this century there was no specific remedy for schistosomiasis, though emetine had for some time been used as a secret remedy in Egypt; then McDonagh[1] and Christopherson[2] independently showed the value of tartar emetic. There was little further advance in the treatment of schistosomiasis for nearly 30 years, though attempts were made to overcome the toxicity of tartar emetic by the introduction of tervalent antimonials such as "stibophen" and "anthiomaline"; these compounds, though less toxic, were less effective. There was much interest, therefore, when at the end of the war it became known that a new series of preparations had been synthesized in Germany by Dr. H. Mauss at Elberfeld. The compounds are known as the miracils—A, B, C, and D. Miracil A is 1-diethylaminoethylamino-4-methylxanthone; in miracil B a chlorine atom is introduced into position 6 of miracil A, and the formula is therefore 1-diethylaminoethylamino-4-methyl-6-chlorxanthone; miracil D, the structural formula of which is here shown, is 1-diethylaminoethylamino-4-methylthioxanthone; and in miracil C the thioxanthone group is replaced by xanthydrol. The most promising of these compounds is miracil D or nilodin, which was shown by Kikuth, Gönnert, and Mauss[3] to be active against *Schistosoma mansoni* in mice. Its pharmacology has been studied by Wood,[4] Hawking and Ross,[5] and Kikuth and Gönnert.[6]

Miracil D cannot be injected, because of the local irritation and necrosis which it causes: by mouth mice tolerate up to 0.3 g. per kg. of body weight, the LD50 (the dose which is lethal for 50% of the animals tested) being 0.5 g. Rabbits tolerate 0.2 to 0.6 g. per kg. without harm, but death occurs after doses of 0.7 to 1.0 g. per kg. In monkeys oral doses of 0.2 g. and 0.4 g. per kg. cause slight diarrhoea, and doses of 0.4 g. and 0.8 g. produce vomiting. Miracils A, B, and C are more toxic for monkeys. In mice infected with *Schistosoma mansoni* miracil B is superior to all the others, but in monkeys it has a curative

effect only when given in doses which cause vomiting, and miracil D is the best preparation. Miracil A, which is only slightly active in mouse schistosomiasis, is more active in monkeys, and miracil C takes an intermediate position both in mouse and monkey tests. All the miracil compounds have a remarkably poor action on immature worms. Even with optimum dosage, however, adult worms do not begin to die until about 14 days after the administration of the drug is begun, but egg production is disturbed within a very few days, as is shown by the formation of eggs without shells, of deformed eggs, and of conglomerations of shells and yolk cells, as well as by the excretion of large drops of shell substance. These changes are associated with degenerative changes in the cells of the testes, ovaries, and yolk-glands and are similar in character to those observed by Vogel and Minning[7] in *S. japonicum* when acted on by tartar emetic, stibophen, and emetine. Curiously enough, none of the miracils has any action whatever on experimental infections due to *S. japonicum* in rabbits, hamsters, and monkeys.[8]

Because of the results obtained in animal experiments, miracil D was selected for clinical trials, and tests have now been carried out in Egypt[9-11] and in Southern Rhodesia.[12] In Egypt doses up to 7.5 g. were given in eight days to patients with *S. haematobium*. With the highest doses permanent cures were usually obtained, but there was some evidence of toxicity. The blood concentration of miracil D, and presumably its toxicity, are raised when the renal functions are impaired. In Southern Rhodesia daily doses ranging from 35 to 150 mg. per kg. of body weight were given to boys and young adults for 10 days. Fifteen weeks after the end of treatment 12 of 18 patients appeared permanently cured. For reasons not yet explained symptoms of toxicity were much less pronounced than in Egypt and consisted mainly of abdominal pain, nausea, vomiting, slight disorientation, and cough. The frequency of these symptoms was not related to the size of the dose and seemed to depend, at least partially, on personal idiosyncrasy. Very occasionally herpetiform eruptions are seen both with miracil D and with tartar emetic; possibly, therefore, the condition may be due to allergy from disintegrating schistosomes rather than to drug toxicity.

S. mansoni seems to be less sensitive to miracil D than *S. haematobium*. In Southern Rhodesia only 1 of 14 patients was cured. In Egypt results are difficult to evaluate because of the small number of patients treated and the numerous dose schedules employed. Blair and his colleagues[12] treated a few patients suffering from urinary schistosomiasis with either miracil A or B. No cures were obtained, but the drugs were not toxic and larger doses might have been effective. Because of the poor results in animals infected with *S. japonicum* it is questionable whether the miracils will be of value in this infection. Although the optimum dose schedules for urinary schistosomiasis have not yet been established, it is obvious that, at any rate in the case of miracil D, a satisfactory alternative to antimony has been found. As a result of the ease with which the drug can be given by mouth, trials are now being carried out on a large scale in particular areas in order to try to break the cycle of infection.

PLANT SOURCES OF CORTICAL HORMONES

Although the treatment of rheumatoid arthritis by "cortisone" ("compound E") must still be regarded as experimental,[1] there is naturally great interest in any method of increasing supplies of the substance. Not only is the present output limited to about 200 grammes per month, but the permanent limitations of the present method of partial synthesis from desoxycholic acid can be judged from the fact that it would be necessary to use the bile acid from forty cattle to obtain the 100 mg. needed daily for the treatment of a single patient over one year. The adrenocorticotropic hormone is equally difficult to obtain in quantity. According to the Armour Laboratories in Chicago, approximately 1,360 hog pituitary glands weigh one pound and only about 1½ g. of ACTH can be extracted from this quantity. All the hogs slaughtered in the United States would not yield much over a pound a week. There is also a growing interest in the cortical hormones generally, and an increasing need, therefore, for some alternative source of supply. According to an announcement[2] reported to have been made last week by representatives of the U.S. Public Health Service and the Department of Agriculture such an alternative source has now been found in sarmentogenin, a substance which was isolated in 1915 (but not then determined) by Jacobs and Heidelberger, of the Rockefeller Institute for Medical Research. The discovery was made during the investigation of seed samples from the plant genus *Strophanthus*, from which strophanthin is derived. The sample in question was a commercial one and was wrongly labelled as from the species *S. hispidus*—one of those used by African tribes as a source of arrow poison None of the original seeds had been kept, and it was only after a number of years that another sample was obtained—this time from seeds of *S. sarmentosus*—which yielded the same substance. The plant is a tropical vine which may grow to a height of eighty feet or more. Besides growing in Africa, it is found also in India, Burma, the East Indies, and the Philippines.

More recently it has been shown that with sarmentogenin as the starting-point cortisone can be prepared with 20 intermediate steps instead of the 37 the present method entails, and that a ton of seed could provide enough cortisone to treat one patient for a year. This would be a useful simplification, but still a long way from an ideal method of manufacture. Although both seeds and plants have been collected from Liberia by an expedition led during the present summer by Dr. J. T. Baldwin and sponsored by the Federal Security Agency and the Department of Agriculture, it is pointed out that five years would be needed before plants raised from seed would be in bearing. None the less, the project of large-scale cultivation under equatorial conditions is being contemplated, and a further appropriation is being sought for a wider investigation of plant sources of animal hormones. If the therapeutic value of cortisone as at present prepared is established, then its preparation on a larger scale will become more practicable. Further, the partial synthesis of other cortical hormones may be simplified.

THE MENTAL HOSPITAL POPULATION

BOARD OF CONTROL REPORT

An account of the mental health services of England and Wales was recently for the first time incorporated in the annual report of the Ministry of Health (*Journal*, Aug. 13, p. 381). To satisfy a provision of the Lunacy Act, however, an annual report has to be made by the Board of Control to the Lord Chancellor, and this, which has just been issued, contains some further details. The number of persons under care under the Lunacy and Mental Treatment Acts at the end of 1948 was 144,725, of whom 140,915 were in hospitals now vested in the Minister of Health. The designation of mental hospitals is said to have proceeded smoothly in spite of complications resulting from the fact that many former public assistance institutions were continuing to accommodate mental patients and a good deal of sorting out had to be done and is still continuing. On the basis of recognized standards there is considerable overcrowding in the former county and county borough mental hospitals, and it was worse at the end of 1948 than it had been at the beginning of the year. The main problems are shortage of staff, unreleased beds, and lack of new building. The nursing shortage has been somewhat ameliorated by the recruitment of part-time nurses, though it is hinted that this arrangement is not altogether satisfactory in mental hospitals. But according to the reports of the individual commissioners who have made statutory visits to various institutions the shortages have not adversely affected the welfare of the patients, thanks to the efforts of the medical and nursing staff, to whom the Board pays a tribute.

The death rate in 1948 was 6.26% of the average number resident, being 1.36% below the rate for the previous year. Tuberculosis continues to occur more frequently in mental hospitals than among the general community, and this year, owing to intensified methods of *x*-ray examination, there was a slight increase in the number of cases discovered, but the death-rate from tuberculosis fell from 5.5 per 1,000 patients resident to 4.7. Gastro-intestinal infections, on the other hand, are said to be more rare proportionately in the mental hospitals than outside them. Less than one patient in a hundred is so affected, and the death rate is less than one per 10,000 persons resident.

In the view of the Board the documentation of certified patients continues to be unsatisfactory. In one quarter of 1948 an investigation was made, and it was found that, out of 6,156 documents for temporary and certified patients received, 384 had to be returned for amendment on medical grounds and 1,291 for amendment for technical reasons; ultimately in each category 55 were rejected.

From the tables which appear at the end of this brief report it is shown that in the designated mental hospitals and the teaching hospitals there are 60 Health Service patients to one private patient, but in premises not vested in the Minister the proportion is reversed. There was a large decrease (over 7,000) in the number of private patients during 1948 and a corresponding increase in the number of Health Service rate-aided patients. The number of voluntary patients in hospitals and under care of all kinds was 21,788 and of certified patients 123,464. Of the total number of persons suffering from mental disorder and under care about 57% are females, who predominate in every category, except that of Broadmoor patients. The Broadmoor population is just upon 1,000, of whom only one-fifth are women.

The Ministry of Food has reminded retailers that where an additional quantity of butter and margarine together is specified on Form R.G.48 issued to diabetics the *maximum* amount allowed is 10 oz. of butter and 10 oz. of margarine. This means that diabetics are entitled each week to 6 oz. of extra butter and 6 oz. of extra margarine in addition to the normal weekly ration of 4 oz. of butter and 4 oz. of margarine. Margarine may be taken in lieu of all or any part of the butter ration.

Nova et Vetera

WILLIAM WALWYN, "HEALTH'S STUDENT"

The name of William Walwyn is as familiar to the political and social historian as it is unknown to the medical historian. This is not surprising, for only in recent months has the celebrated leader of the "Levellers," the associate of Lilburne and Winstanley, been identified with the obscure unlicensed practitioner who wrote *Physick for Families*.

Many of our younger historians are making a special study of the English Puritan revolution. One of the most recent products of this revived interest is a book[1] by Dr. W. Schenk, lecturer in economic history at Exeter. The third chapter of this book is devoted entirely to Walwyn, and Dr. Schenk's account supplements and corrects the entry in the *Dictionary of National Biography* in many particulars.

Born in 1600[2] at Newland, Worcestershire, William was the son of Robert Walwyn, gentleman, and of Elizabeth, daughter of Herbert Westfaling, Bishop of Hereford. After apprenticeship with a silkman in Paternoster Row he became a member of the Merchant Adventurers' Company and maintained a large family "in a middle and moderate but contentful condition." One of his daughters married Humphrey Brooke, F.R.C.P., who may have influenced Walwyn in the choice of his later career and whose own written works reflect the influence of Walwyn's social and religious views.

Walwyn's career between 1642 and 1649, when he spent eight months in the Tower with Lilburne, accused by Cromwell of fomenting mutiny in the Army, belongs to English history and is adequately dealt with by Schenk.

"Physick for Families"

While working on his book in the Bodleian Library, Dr. Schenk came across the 1681 edition of *Physick for Families*, by William Walwyn, which has a portrait frontispiece, engraved by R. White, of the author at the age of 80.[3] Collating this with the information given in the Newland parish register and in a published pedigree of the Walwyn family,[4] which states that William Walwyn, M.D. (*sic*), of London, son of Robert Walwyn, of Newland, married and had several daughters and died *circa* 1680, Schenk identifies the author of the book with Walwyn the Leveller. Final confirmation was given by the discovery of Walwyn's will in Somerset House. This is dated 1680 and was proved on Jan. 14, 1681.

Schenk seems to be unaware of any other medical book by Walwyn or of any other edition of the *Physick for Families* (which he thinks was published posthumously and possibly commemoratively), so that his account of Walwyn's medical career is necessarily vague, although there is evidence in the 1681 edition of the *Physick* that Walwyn may have been practising as early as 1665, during the "great Mortality." It is no reflection on the thoroughness of Dr. Schenk's researches that his results were so limited in this respect, for the 1681 *Physick* is indeed the only medical book with Walwyn's name on the title-page. Apart from the Bodleian copy there is one at the Royal Society of Medicine; copies of a 1696 edition are to be found in the British Museum and in the Army Medical Library at Washington. But there *were* earlier editions—one in 1669, presumably the first; and another in 1674. Both editions are in the Wellcome Historical Medical Museum and in the Cushing Collection in Yale Medical Library. In addition, there is a book called *A Touchstone for Physick* published anonymously in 1667, copies of which survive in the British Museum (catalogued

[1] *The Concern for Social Justice in the Puritan Revolution.* London, Longmans, Green, 1948. Pp. 41–63.

[2] According to the Newland parish register he was baptized on Aug. 17, 1600. *The Dictionary of National Biography* has (fl. 1649) and its account does not go beyond the year 1651.

[3] This portrait is reproduced as the frontispiece of Dr. Schenk's own book.

[4] *Visitation of the County of Worcester, 1682–83.* Edited by W. C. Metcalfe. Exeter, 1803, p. 100.

[5] *Dictionary of Anonymous and Pseudonymous English Literature*, 1926–34. Vol. 6, p. 65.

under W. W.) and in the Wellcome Historical Medical Museum. This work is correctly attributed to Walwyn by Halkett and Laing.[5]

It is thus possible to state that Walwyn was practising medicine certainly before 1667, and there is internal evidence that he was practising for some years before his *Touchstone* was published. On page 81 he declares that the value of his medicines had been proved

> "even in the Pestilence it selfe, for though I staid not in London past the increase of two Thousand a Week; but was forced away or must be cruel where all obligations of tenderness lay upon me: yet took I care that nothing of mine should be wanting to any who desired to make use of them; with some liberty of freely helping the necessitous: besides *I had long declined Practice, visited none, nor had then so* much as one Patient under my Hand: and withall had so published the Vertues and Uses of all my Medicines; as sufficed both to encourage and to instruct every one so plainly, as without further direction or attendance, every one might be in a capacity of helping themselves and their relations upon any occasion."

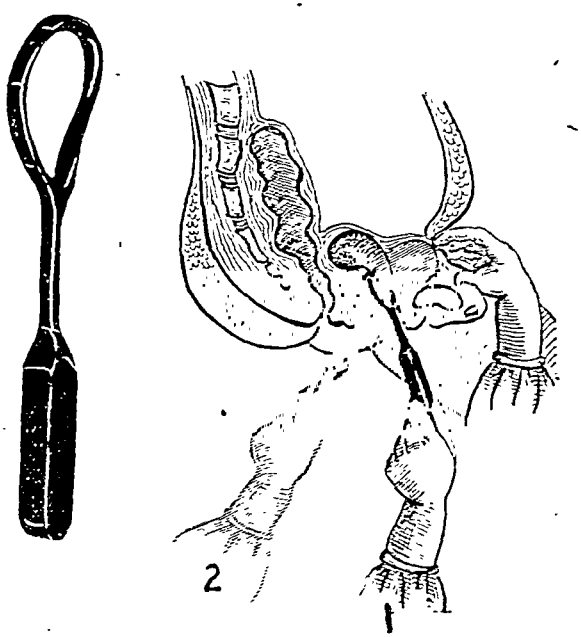
On page 84 he refers to "one who practised much with them [his medicines] long before, and from the beginning to the ending of that sad Mortality." The preface to the book is signed W. W., and at the end is the address, "At the Star in the Postern by little Moorefields, London, 1667."

The 1669 edition of his *Physick for Families* is also anonymous, but the preface is signed "W. W. Healths Student" from the same address. The 1674 edition has his initials and address on the title-page, and begins, without preface: "Having now past through many years Practise, in this my new way of Physick; And with God's blessing in, and upon my peculiar Method and Medicines, been most happily successefull, in abundance of very threatning, dangerous Distempers. . . ."

Walwyn's Method and Medicines

What were his "peculiar method and medicines"? The answer to this question fills the last gap in our knowledge of Walwyn and of his career as reformer and physician. They consisted of an uncompromising repudiation of all the fashionable medical procedures of his day, such as purging, bleeding, vomiting, issues, clysters, and the indiscriminate exhibition of mineral drugs, and the renunciation of polypharmacy and all the evil-smelling and foul-tasting mixtures which made up the greater part of the seventeenth-century pharmacopoeia. He advocated a mild expectant treatment, aided by the patient's co-operation and his own "peculiar medicines," which were 32 in number, each one appropriate for a particular "mark or character of disease." He does not tell us what went into these medicines, but assures his readers that they were all pleasant to the sight, smell, and taste, liquid in form, and generally of a clear and sparkling character.

His books largely consist of case histories in which the virtues of his treatment are vindicated by a successful outcome. He informs us that he declined "the common Road of Physick" (he had no medical qualification) for no other cause "but for its manifest uncertainty in Principles, Roughness, Harshness and Cruelty in Methods, Impropriety, Impotency and danger in Medicines." Instead, he sought to blaze his own trail as a "Healths Student," probably influenced by his son-in-law, Humphrey Brooke, whose book *A Conservatory of Health* (1650) stresses the value of preserving health rather than curing disease.



The medical historian, while introducing a new figure into the gallery of medical men who have left their mark on history, and while applauding the originality which led Walwyn to reject the therapy of his day before the scientific reasons for such a rejection were enunciated, may yet criticize the unscientific character of his books. Walwyn gives his own answer: "I conceive my charitable intentions sufficiently justified by the Text: The truly Christian Vertue of *Compassion*, being as essentially needful in a Physitian, as in the most tender hearted Samaritan."

F. N. L. POYNTER.

Preparations and Appliances

UTERINE ANTEVERTOR

Mr. MCKIM MCCULLAGH, surgeon, Samaritan Hospital, London, writes: For those elect few among general practitioners, consultants, and specialists in gynaecology who believe that a fully retroverted uterus can cause such symptoms as backache, dyspareunia, menorrhagia, premenstrual depression, headaches, and even nausea, not to speak of sterility and miscarriage, I can recommend the antevertor depicted in the diagram and made by A. L. Hawkins, Ltd., of 15, New Cavendish Street, London, W.1, as a helpful instrument.

Normally one endeavours to antevert the uterus with the fingers by pushing upwards in the posterior fornix and then changing the finger-tips to the anterior fornix and pushing the cervix backwards. The left hand is kept on the abdomen ready to contact the fundus uteri and pull it forward. For those with short fingers the procedure is difficult, especially in a patient with a long vagina. A long narrow Hodge pessary grasped by the thumb and first two fingers at its lower end is often used to transmit the push to the posterior wall of the corpus uteri, which causes it to move forward and upward from the floor of the pouch of Douglas.

The vulcanite antevertor here depicted saves the patient some of her discomfort and the specialist mental and physical strain. It is easy to introduce and use, and causes no pain or pressure at the vulval orifice. The lift and degree of pressure on the posterior fornix are easily regulated, as the handle of the instrument is well outside the vulva and is used as if it were the handle of a long spoon. The lift and pressure on the posterior wall of the uterus should be as high in the posterior fornix as possible, and it should be slow and gradual and always short of causing appreciable pain to the patient. find anteversion of the uterus much easier to attain with t antevertor than with the fingers or a Hodge pessary. W anteversion is attained and the uterus pulled and flexed forward, a suitable Hodge or ring pessary is inserted. three days a marked improvement in comfort and ment look frequently follows and definitely warrants the ad surgical treatment in the form of a ventrosuspension o

Reports of Societies

FRIENDS OF THE HEBREW UNIVERSITY

London Dinner

The Friends of the Hebrew University held a dinner at the Park Lane Hotel on July 21 to celebrate the opening of the new medical school in Jerusalem. Professor SAMSON WRIGHT, who presided, remarked that the representative gathering reflected the widespread interest in this country in the new institution. He had received many messages of good will, including one from Sir Henry Dale, who had expressed his high hopes of the school. Professor Wright pointed out that the annual budget of the Hebrew University was now some £700,000. The Government of Israel made a grant of £50,000, but the large balance had to be raised by friends all over the world. He referred to the help received from British research funds, and he thanked the British Government for granting the University facilities to acquire surplus scientific equipment on generous terms. He hoped that the dinner would mark the re-establishment of the cordial relationships which had always existed between the Hebrew University and the British scientific, academic, and medical world.

The Minister of Israel, Dr. MORDECAI ELIASH, said there were some 3,000 doctors in Israel to serve a population of less than a million, or roughly three times as many doctors as are required by an ordinary community. During the first five months of this year 500 doctors had arrived in Israel, which, taking full account of the immigration during that period, still maintained the proportion. But most of these doctors had passed the prime, and the number of young practitioners was alarmingly small. On the other hand, the number of hospital beds was still much below the normal requirements of the country, only 3,000 being available instead of the normal eight or nine thousand.

For some years there had existed a pre-faculty of medicine of the Hebrew University of Jerusalem. In the year 1946–7 appreciable progress had been made and a new building was laid down on Mount Scopus. On May 17, 1949, the first 45 students from among 200 applicants were enrolled. They were mainly Israel medical students who were recalled from abroad to serve in the Army. The medical school would be the best memorial to the three men—Dr. Yaski, Dr. Doljanski, and Dr. Ben-David—who were its leading planners and who lost their lives in the Mount Scopus massacre in April of last year.

Sir HENRY COHEN referred to his life-long connexion with the Hebrew University, of which he was a Governor. He paid tribute to the work of the University hospital staff and its scientific workers in coping so successfully with the grave problems resulting from the prolonged siege and military operations in Jerusalem. He commented on the meagre salaries now paid to the academic staff of the University, and hoped that resources would soon be available to enable their remuneration to be raised.

Dr. REDCLIFFE SALANSON, F.R.S., proposed the toast of the guests, who included Lord Horder and Dr. H. E. A. Boldero. Dr. ARTHUR FELIX, F.R.S., responded.

Next month the Manchester Municipal College of Technology is to begin a series of evening courses for laboratory technicians. These courses are intended to supplement their daily work in the laboratory and to help them prepare for their professional examinations. Both scientific and medical subjects will be taught. There will be an intermediate course in the elements of laboratory technique in pathology, bacteriology, chemical pathology, and haematology, and four independent final courses in each of these subjects. At the end of the final course the student will take the corresponding final examination of the Institute of Medical Laboratory Technology.

Correspondence

Distinction Awards

SIR,—The very important letter from Dr. F. M. R. Walshe (Aug. 13, p. 383) is not likely to go unanswered, but the signatories of this letter, all members of the consulting staff of a teaching hospital, wish to express their whole-hearted agreement with everything said by Dr. Walshe. As he pointed out, the Awards Committee has a wholly impossible task, and it seemed only too probable that in an attempt to solve their problems they would be compelled to adopt methods of obtaining information which are both undesirable and invidious. There can be no doubt that consultants are not all of equal merit and that therefore some are worthy of special distinction. We would submit, however, that the academic distinctions of the past will remain in operation (the Member of the College will strive for the Fellowship, the Fellow may be elected to the Council), and private practice still remains at the disposal of those who feel that their merit deserves remuneration.

We hope with Dr. Walshe that it is not yet too late to abandon the idea of distinction awards in its present form.—We are, etc.,

MAXWELL TELLING.

Leeds.

SIR,—Not only teaching-hospital committees but committees for professional assessment in hospital regions have been asked for recommendations for merit awards, and, difficult as the job is, it is being tackled. What is the alternative? How are consultants to be paid? To reject the considerable sums of money offered would be hard on some men. The method of distribution put forward by the Spens Committee at the suggestion—it is understood—of a distinguished layman is supported in principle by the Consultants and Specialists Committee of the B.M.A.

The range of qualities and skills among consultants is of course vast, and grades do not exist except in the mind of the observer. In the past incomes have been vastly variable also. But can we say, when we look at the incomes tabulated in the Spens Report and remember able men earning much less than they deserved, that the old method was really good? When we remember such men, surely we grade them in our minds, just as we have always graded fellow consultants, though not by finding out who earns the most, when sending our patients—or taking our relatives and ourselves—to them.

In spite of philosophical doubts, then, if we are honest with ourselves we admit we have acted as if grades existed, though we have gone to some trouble to conceal the fact. We are now asked to express the opinions which guided us up to July 5, 1948. It is not easy: if another method of letting consultants get what they need can be produced nobody would be more glad than I. But to reject this scheme without producing one as good, or at least feeling sure that the method that worked before the Health Service began would work better now, is to do something very drastic. All political parties are determined on a health service, and it happens that in the one proposed to us a consultant is rewarded less according to his prestige with the laity and more according to the opinion of his fellows. It is a defensible point of view.

The decisions ought not to be made by only a few, however, and it seems from information given to regions that they will not be. Recommendations will come from several directions and be referred in several directions again. One direction from which they will come (and on this the Consultants and Specialists Committee has been emphatic) must be local. It

is impossible to judge without local knowledge. But this, we understand, is only one source of information: to place sole responsibility there would be too heavy a task altogether, and we do not think it is contemplated.

For this responsibility is deeply felt. People who accept it do so because they believe the profession is faced with political and economic facts which can only be ignored to its certain disadvantage, and they are not prepared to ignore them. If consultants as a whole refuse extra pay then assessment committees can rest at last. But unless consultants do refuse the money the committees must do their best.—I am, etc.,

Hove, Sussex. W. A. BOURNE.

SIR,—Dr. F. M. R. Walshe (Aug. 13, p. 383) has again done a great service to our profession by attacking the whole conception of distinction awards, but he has ignored at least two of its weaknesses. First, if recommendations are to be made by subcommittees of hospital medical committees it seems clear that the members of such subcommittees will have to be chosen from among those who are considered to be unsuitable for a merit award—an invidious task for the chairman of the medical committee. Secondly, as chairman of the medical committee of a non-teaching hospital I have not received one of the signed circular letters. Is it to be assumed, therefore, that only the staffs of teaching hospitals are eligible?

There have been previous attempts to weaken the precarious unity of the medical profession: they failed. Let us be careful that the bait of financial benefit does not split the consultants into envious groups.

If there is, indeed, some money available it could be employed in a much more fruitful way. Thus we were promised that anybody would be allowed to use the whole of the facilities of the N.H.S. or any part of them. Since then the Minister has refused to allow private patients to use that part of the service that consists of receiving free drugs, using as his excuse the nonsensical statement that medical advice and treatment cannot be separated from one another. Oddly enough, he does not hold that this indissolubility holds in surgery: everyone is entitled to be a private patient and yet to be operated on gratuitously in hospital. It is, I think, impossible to escape the conclusion that the Minister thinks that the granting of the right to receive medicines without direct payment for them would wreck his scheme, because so many people would choose to be private patients.

Whether this would be so or not is a matter of opinion and need not be discussed at the moment. What is, however, relevant to my remarks is the reply of Mr. Blenkinsop to Mr. H. D. Hughes (*Journal*, Aug. 13, p. 393). He said that if the estimated annual rate of expenditure on the pharmaceutical services were proportionately increased in respect of the 5% of the population not on doctors' lists the increase would amount to about one million pounds. If this expenditure were undertaken private practice would undoubtedly revive. And consultants would do as they did in the past—they would build up practices. Then the various kinds of "distinction" in medicine would have their chance to add to their possessors' incomes, while the Distinction Awards Committee, having no part to play in assessing the status of members of a learned profession, could be disbanded.—I am, etc.,

London, W.1. A. PINEY.

SIR,—I hope that Dr. F. M. R. Walshe's admirable letter (Aug. 13, p. 383) will rouse us to action. The vast majority of doctors consider the distinction awards a ludicrous suggestion, and it is well recognized that an equitable manner of selection of individuals to receive such awards is a frank impossibility. It seems incredible that members of what has been for so long an honourable profession should become commercialized so rapidly that they may be willing, as Dr. Walshe aptly says, "to be priced as though they were professional soccer players." Must distinction in our profession now be assessed only in terms of pounds, shillings, and pence paid through a Ministry?

In the eyes of the general public our professional prestige has already been sadly dimmed by what appears to be our undue concentration on the monetary side in our negotiations with the Ministry. Are they now to be diverted by the spectacle of those who should be the leaders of our profession sitting in solemn conclave dispensing first-, second-, and third-class distinction awards, payable in cash, to their colleagues? We expect a better moral lead from those in high places.

I have the honour to sit on two committees to which the request from the chairman of the Distinction Awards Committee has been made for guidance. Cynical laughter is the instant reaction in any medical group where the subject is mentioned. Nevertheless, when it is suggested that we shall have nothing to do with this farcical plan, fears are expressed that by inaction we may be doing an injustice to colleagues in our own hospital or specialty and that other bodies may make recommendations although we refuse.

Surely it is high time that we ceased to be guided by such a policy of expediency. These fears of possible consequences have insidiously broken down too many of our defences already; they are all too reminiscent of the successful Nazi method of producing an attitude of cynical defeatism. If, as individuals, we feel a policy is wrong we ought to have no hesitation in making a stand now against a scheme which must lead inevitably to jealousy, suspicion, and discord among members of our profession. As individuals and as members of any professional body to which we may belong we should rouse ourselves from a state of apathetic acquiescence and protest against this attempt to put a financial value on that invaluable and indefinable thing—professional distinction.—I am, etc.,

London, N.W.1. KATHARINE LLOYD-WILLIAMS.

Poliomyelitis Precautions

SIR,—In your leading article (Aug. 6, p. 323) you advise doctors to keep children at home who are suspected of being in the pre-paralytic stage of poliomyelitis. I feel that this is an unwise recommendation, for it is very liable to cause delay in the diagnosis of meningitis, particularly tuberculous, which is very apt to be confused with poliomyelitis in the early stages. The prognosis of tuberculous meningitis depends largely on early diagnosis.

Only last week a child was admitted to this hospital in deep coma as a result of tuberculous meningitis: he had been watched at home for a fortnight as a suspected case of poliomyelitis. In my opinion a case of suspected poliomyelitis, especially if there is meningism, should be admitted immediately to hospital for investigation.—I am, etc.,

The Children's Hospital, Sheffield. J. LORBER.

What is Social Medicine?

SIR,—May I say that I have long shared Dr. Thomas Gibson's uncertainty (Aug. 13, p. 388) as to the meaning of the term "social medicine," and have asked repeatedly and in vain for a satisfactory definition. If Professor W. Hobson's extremely comprehensive description (July 16, p. 125) is accurate, then surely the term "psychosocial medicine," which is already in use, would be the more appropriate.

But my difficulty here is that a few years ago, when a "strong" subcommittee of a famous hospital was considering an appointment in this "new" specialty, neither its department of public health nor its department of psychological medicine was represented on the subcommittee or consulted in any way on the matter.—I am, etc.,

London, W.1. HENRY YELLOWLEES.

Conceptions of Right and Wrong

SIR,—The question of the adequacy of the M'Naghten rules to express or interpret modern knowledge on the subject of responsibility is raised afresh and in a prominent form in your report on the Haigh trial (July 30, p. 286).

As is generally known, the two questions requiring proof in any individual case in which the subject of responsibility is

raised are that the accused person was not aware of the nature and quality of the act he was doing or that he did not know that what he was doing was wrong. I would very much like to be authoritatively informed of the meaning of the word "wrong" in this context. My opinion is that it has been generally employed to signify wrong in the moral sense, the meaning that the average rational individual in this country—i.e., living in our particular form of culture—would give it.

But the prosecuting counsel, Sir Hartley Shawcross, at the Haigh trial gave a different interpretation to the term. He is stated to have put to the medical witness the question: "I am not asking you whether the man decided, in obedience to a higher power, to do what he realized was wrong; I am asking you to look at the facts and tell the jury whether there is any doubt that he must have known that, according to English law, he was preparing to do, and subsequently did, something which was wrong." I submit that this is not the meaning of the word "wrong" intended by the M'Naghten rules. I say this because, in the first place, there have been many trials in which it has been interpreted in the ordinary moral sense. A not uncommon example is the case of the mother who in a state of depression kills her child in order to save it from the suffering she imagines is in store for it. She may be aware of what she is doing, may know that it is against the law and that she will be punished for it, but she considers it right and justifiable in the light of her strong (abnormal) convictions.

In the case of M'Naghten himself, from what is known of his state of mind we can draw the highly probable conclusion that he knew what he was doing when he shot Sir Edward Drummond and also that he knew that "according to English law" what he was doing was wrong. At the same time his judgment of right and wrong was so impaired by his delusions of persecution that it was obvious to the court that he was of unsound mind. If, however, the same test had been applied to him as was applied in the case of Haigh, M'Naghten would not presumably have been found insane at the trial.

In the second place it is to be noted that the statement of the two tests setting out the legal conception of responsibility contains the disjunctive "or" (did he know the nature and quality of the act or (*sic*), if he did know it, did he know that what he was doing was wrong). The disjunctive implies that there is a significant difference between the two tests. But the fact is that in the great majority of cases in which the prisoner knew what he was doing he would also know that what he was doing was wrong "according to English law." He may, nevertheless, firmly believe that what he was doing was right according to his conscience and his own conception of right and wrong.

It is clearly a matter of great importance to know, without equivocation, what is meant by "wrong" as used in the M'Naghten rules. It can hardly be seriously contended that it is justifiable to allow it to signify wrong according to English law in one case and morally wrong in another.—I am, etc.,

London, W.1. FREDERICK DILLON.

Treatment of Infantile Gastro-enteritis

SIR,—Dr. C. Zahra Neumann (July 16, p. 132) is to be congratulated on a novel interpretation of part of the symptomatology of infantile gastro-enteritis, and further work will be needed to substantiate the hypothesis that the histamine bodies are responsible for some of the intoxication seen in this group of diseases.

The paper, however, does not support the claim made that a combination of antihistamine drugs plus sulpha derivatives are more effective than the sulpha derivatives alone. The sedative effect of "benadryl" is central in action, and this, by producing rest and sleep, would in itself reduce the general discomfort, irritating whine, tachycardia, and even prostration (many years ago injections of nepenthe were used for this purpose). No figures are given which could enable one to compare mathematically the reduction in number of stools in the two methods of treatment—the graphs given do not contain sufficient information for statistical analysis.

In the group treated by sulphamezathine alone (method A) there are 3 deaths in 42 cases; in the group treated by sulphamezathine plus benadryl (method B) there is 1 death in 40 cases. Now the percentage difference between A and B is $7\% - 2\frac{1}{2}\% = 4\frac{1}{2}\%$; but the standard error is 5.57%, and as the percentage error is less than twice the standard error there is no statistical significance between these figures. Furthermore, using the exact method of χ^2 for a 2×2 table, it can be shown that the probability is 0.33, which means that we can expect this difference (of 3 deaths in 42 cases and of 1 death in 40 cases) to occur 33 times in every 100 experiments. In other words this difference in mortality is an event quite likely to occur by chance and no conclusions can be drawn from it. It is clear that much larger numbers of cases will need to be investigated before this claim can be substantiated.—I am, etc.,

London, W.9. C. A. ROYDE.

Syringes

SIR,—Anyone contemplating the initial expense of a syringe service should note that the British Standards Institution has recommended the Luer fitting, and the specification in British Standard 1263 covers metal-and-glass as well as all-glass syringes. As a consequence, at least one manufacturer is now marketing syringes only of standard specification, and it seems likely that the Record fitting will be superseded and that in a few years replacements in bulk may be difficult.

The general adoption of the Luer fitting is obviously desirable, as pointed out by Dr. D. Gairdner (July 30, p. 282), and I am told that an attempt was made to adopt it after the 1914–18 war. The market was soon flooded, however, with cheap Record syringes from Germany, and English manufacturers had to conform in order to compete. A repetition of this is unlikely, and anyone making a stock of syringes should begin with the Luer pattern, for economic reasons as well as those given by Dr. Gairdner.—I am, etc.,

Broxbourne, Herts. T. C. BEARD.

Essential Hypertension in Pregnancy

SIR,—Mr. John Sophian's letter (Aug. 6, p. 335) is of interest. The idea that "functional vascular spasm" is the primary change inducing hypertension, and that it is the cause of "renal cortical ischaemia" in pregnancy, when the renal arterioles are affected—or that it is the cause of the anuria occurring in elderly men with enlarged prostate in whom the greatly distended bladder has been emptied too rapidly—is unsatisfying. Attributed in the former to "sympathetic overactivity," the cause of this overactivity remains unexplained. Nor can I understand how in puerperal anuria Bowman's capsules and the renal tubules should become so greatly distended—with urine—if the condition is caused by a primary occlusion due to vascular spasm of renal arterioles. A picture of this change was given twenty years ago by Clifford White (*Proc. R. Soc. Med.*, 1919, **12**, 29), and his sections were shown on the screen at an R.S.M. meeting in January of this year. Those seeking an explanation of the cause of the acute changes in the kidney associated with oliguria or anuria, whether in the pregnant or not, should take this distension into account. My criticism of the work of Trueta and his colleagues is that nowhere in *Studies of the Renal Circulation* have I found any reference to the effect of the secretion of urine on the blood flow through the kidney. It is of fundamental importance.

Very interesting is Mr. Sophian's comment on Dr. Hingson's treatment of eclamptic patients by means of controlled spinal analgesia. In 1928 I published my first case treated with spinal analgesia (*Proc. R. Soc. Med.*, 1928, **21**, 70). It was received with scepticism. I believe it was tried, but I think more to demonstrate its unworthiness than any virtue it might possess. The mind of the demonstrator matters. I have had several similar experiences. In 1932 I treated a man who had developed anuria some time after an abdominal operation. Two injections were given at an interval of twelve hours, and the result was wonderful. It was so wonderful that I had the greatest difficulty in getting the paper published: everyone seemed to think the experience related was not true.

Finally, it was published in abridged form in 1935 (*Lancet*, 2, 554). The patient, a farmer, is still strong and well—I see him occasionally by chance in the street.

In my view spinal analgesia acts by inducing a state comparable with shock. There is a great fall of blood pressure, and blood is not thrust into the renal medulla to maintain the obstruction to the exit of urine from the uriniferous tubules. The treatment should be induced early: there is no point in delaying. The position of the patient is important. He (or she) should be kept in the Sims position, with the foot of the bed elevated, and starved completely, with great limitation of fluid. More than one injection is usually required. In fulminant eclampsia it is better to try such a treatment than let the patient die. In post-partum anuria it is much better to do this than use an artificial kidney, for the application of the latter is vain at a time when the cortical renal cells are rotting.—I am, etc.,

Rugby. R. H. PARAMORE.

Strangulated Appendix in Femoral Hernial Sac

SIR,—The following case report may be of interest to your readers.

A woman, aged 67, was admitted to St. Leonards Hospital on May 6, 1949, with a diagnosis of strangulated femoral hernia. She was collapsed and dehydrated, with a subnormal temperature, a blood pressure of 100/70 mm. Hg, a pulse of 120, and a respiratory rate of 28. Two days before admission she had complained of intense abdominal pain, most marked in the right iliac fossa. Vomiting began simultaneously, the vomit being first yellowish, later brownish, and, on admission, faecal in character. She had had no bowel action and had not passed flatus per rectum for three days. She had a tender lump about two inches (5 cm.) in diameter in the right femoral region; there was lower abdominal tenderness and a certain amount of distension. A diagnosis of strangulated femoral hernia was made.

At operation a longitudinal incision was made over the lump and the hernial sac was exposed and opened. The appendix was lying in the sac and was thickened, obstructed, and congested, with haemorrhagic patches on its walls. The neck of the sac was very narrow and was obviously obstructing the appendix; the proximal quarter-of-an-inch (0.6 cm.), which was inside the abdomen, was normal in colour and size. The herniated part of the appendix (two inches long) was removed, and the mesoappendix divided and ligated. The stump could not be buried in the wall of the caecum, but as there was a long mesoappendix it was buried in that structure. The sac was ligated and divided, and the femoral canal closed by suturing the inguinal ligament to the pectineus fascia. The patient made an uneventful recovery, and was discharged from hospital on May 20, 1949.

I am indebted to Dr. A. D. Morris, medical superintendent of St. Leonard's Hospital, for his advice and permission to publish this case.

—I am, etc.,

London, N.1. S. P. BOFFA.

Torsion of Normal Fallopian Tube

SIR,—I have read the article by Mr. R. de Soldenhoff (July 30, p. 263) and Professor Lambert Rogers's letter (Aug. 13, p. 384) on the subject of torsion of the normal Fallopian tube, and I should like to add a further case to the literature.

I was called out to see a girl, aged 13, who had not yet begun to menstruate. She complained of colicky abdominal pains for the past four days, situated mainly in the left iliac fossa, and had vomited on the first day of her illness. Three weeks previously she had suffered from a similar attack which had lasted three days, and she had then felt well again. She was constipated and looked ill and toxic.

On examination her temperature was 100.4° F. (38° C.) and the pulse rate 96. Her tongue was furred and moist. Her abdomen felt soft, without any guarding, but she was tender to pressure in the left iliac fossa. A rebound phenomenon was present in both iliac fossae. Peristalsis was diminished. She was extremely tender in the anterior walls of her rectum, and she was *virgo intacta*.

The diagnosis of a lower abdominal peritonitis, due possibly to a perforated appendix or a perforated Meckel's diverticulum, was made. During the next few hours in hospital her pulse rate rose to 114 and she did not improve.

At operation there was a small amount of blood-stained fluid in the peritoneal cavity. The left tube and ovary formed an impacted reddish-blue mass in the pouch of Douglas. They were released with difficulty. The tube was gangrenous, due to two complete twists of its mesosalpinx. The ovary contained a blood-stained cyst. A left salpingo-oophorectomy was carried out, and the patient had an uneventful convalescence. Section of the tube showed it to be *normal, but it was obliterated by blood.*

This case is one of undoubted primary torsion of the undiseased Fallopian tube in a girl before menstruation had commenced. As the aetiology is unknown, its main importance lies in the difficulty of diagnosis, for there is no definite syndrome to recognize. Because it occurs in young people and the diagnosis is in doubt, I venture to disagree with Mr. de Soldenhoff and state that the urgency of operation is great.—I am, etc.,

Liverpool, 9. ALFRED M. ABRAHAMS.

The Common Cold

SIR,—In the *Journal* of Oct. 2, 1943 (p. 433), I stated that as a result of psycho-analytic investigations I had come to the conclusion that the common cold always occurred in association with a particular emotional state which could be defined.

At the meeting of the International Congress of Oto-laryngology, reported in the *Journal* of July 30, Dr. E. P. Fowler (New York) said (p. 278), "In the common cold of all types an emotional factor is very likely to be the precipitating one . . . It is very common for a cold to develop on examination day or on a day of domestic upheaval, evidently due to changes in the nasal mucosa arising from an emotional cause." He added that he believed that a large number of colds were of a neurogenic type, due to overaction of the sympathetic, and that the outstanding prophylactic was emotional equilibrium.

I am glad to have Dr. Fowler's support for my theory. I am quite confident that further investigation of the common cold on psychological lines will confirm the psychogenic origin of this, up to now, mysterious and sometimes dangerous affliction.—I am, etc.,

Leeds. E. WRIGLEY BRAITHWAITE.

Simulated Amnesia

SIR,—I have read with great interest Drs. R. E. Hemphill and J. R. Stuart's article (May 28, p. 938) dealing with simulated amnesia. Do any of us possess hard-and-fast criteria whereby malingering can be distinguished from hysteria?

Very few of us like to use the former term in clinical practice, whereas in legal practice either the term malingerer or the implication that a state of simulated disability exists is frequently made. I take it that the reason for this is that in the majority of such cases the physician sooner or later discovers some underlying cause of worry which explains the response. This does not dispose of the technical question of evaluating the mechanisms whereby an individual symptom complex is produced and maintained—i.e., of explaining the actual pattern of symptoms. A large proportion of the major hysterical patterns can be removed in one session by persuasion. Now although this begs the question of the validity of such forms of therapy if unsupported by more fundamental help it nevertheless reinforces the impression held by many that the hysteric "*could help it if he would*"—i.e., could adopt a more reasonable manner of drawing attention to his need for help.

It appears to me that there are three clinical settings within which the problem of simulation or apparent simulation of, for example, amnesia can occur. (1) The constitutionally averagely endowed man who falsely states that he is ill, knowing that such is not the case. This is true malingering, and is rare in clinical practice. (2) The constitutionally endowed hysteric. In these cases we may be dealing with a prolongation syndrome or elaboration of a nucleus of true dissociative features. This in my experience is the most common clinical problem. (3) The psychotic. Amnesia occurring in schizophrenia is frequently amenable to precisely the same forms of treatment as is the case with hysteria. The more "genuine" the dissociative mechanisms the more grateful the patient. The more conscious the mechanism the more hostile the patient.

When we come to post-traumatic hysteria (neurasthenia) in which litigation is involved we frequently see colleagues in the witness box

stating opposite opinions. For the plaintiff it is neurasthenia, for the defence it is malingering or some oblique expression which implies this. War neurosis cases illustrate the same theme. Some regard the "shell shock" case as a faint heart and sometimes a coward. Others assert he is a sick man. I suggest that in many cases the truth is a combination of both statements. That is to say, when we meet conversion hysteria we can assume that the patient is in distress and to that extent a sick man, but also that mechanisms have come into play which to some extent (varying from patient to patient) are under his control.

When we say that "dissociation" occurs in hysteria we are employing a term which possesses no referrent. This is not to deny its hypothetical validity or indeed its pragmatic necessity, and it appears as if this term describes a class of event which expresses at one and the same time a reaction to emotional trauma and a constitutional capacity for dissociation which the non-hysteric does not possess.

I have seen a pseudochoric maintain his movement for eight weeks to the point of emaciation through inability to eat and sleep, resist narcosis, shock therapy, and what psychotherapy was practicable, and then recover within 12 hours following strong persuasion. I have seen a soldier going about camp with his back bent double for weeks, resist similar methods, and then respond to persuasion in the matter of a few minutes. When the law is concerned with a compensation issue the question of the extent of this control becomes important. I know of no criteria whereby this can be determined. When all is said and done we all "forget" appointments occasionally, tell white lies, lose all emotional control at times, and under stress get palpitations or feel weak at the knees. The hysteric does these things more frequently, for longer, and at times apparently more convenient to his self-interest.

If we are good physicians we do not sit in judgment on him—we seek to understand and try to help. If we are judges or commanding officers or school masters or parents we occasionally have to sit in judgment, and sometimes we reprimand. Now, can anyone deny that a reprimand benefits the hysteric?

Finally, may I reiterate the question which has prompted this letter? Can any psychiatrist assert that he can diagnose with confidence between malingering and hysteria in any individual case? Because if there is such a test medico-legal work in our compensation courts will become easy. The answer to this question would illuminate the manner in which those processes we call dissociation operate, and enable us to understand how a hysteric really thinks and feels about the world. My opinion is that the hysteric can be compared to the "double-jointed person" who possesses the faculty of contorting his frame in a manner not possessed by others. Sometimes this queer mechanism is set going by emotional trauma, and to that extent the patient is a sick person. Sometimes it is set going as a result of the patient's decision to evade responsibility or duty or to establish prejudice in his favour (as in compensation cases). More commonly it is a mixture initially outside his control which becomes prolonged and sometimes, in addition, elaborated. The elaboration features are true malingering, the prolongation features are more or less genuine, and the original nucleus is entirely genuine.

Persuasion is capable of removing the elaborative features but will rarely affect the genuine features except it be exhibited in a manner which introduces still more subtle therapeutic mechanisms. "I seemed to be unable to get better myself: I wanted to but couldn't until you seemed to get me going," as one patient (I believe correctly) assessed the effect of brisk admonitions to a previously intractable pseudochorea. Needless to say, the physician who has the temerity to attempt to treat hysteria by admonition, though invariably receiving the gratitude of his genuine patients, will encounter strong hostility from the non-genuine. Hence the need for accurate diagnosis.—I am, etc.,

Dunedin, New Zealand. HAROLD PALMER.

Paraffin-wax in the Male Bladder

SIR,—I read with interest Dr. T. J. D. Lane's report (July 23, p. 216) on paraffin-wax in the male bladder. I should like to mention a similar case which I encountered in Poland in 1936.

The patient was admitted to hospital with acute cystitis. Cystoscopy confirmed this diagnosis, and to my great surprise revealed a blue-tinted twisted Christmas candle floating on top of the liquid ("rivanol") which had been injected into the bladder for the purpose of the examination. I instilled about 300 ml. of pure benzine into the bladder and after 20 or 30 minutes removed this liquid. I then filled the bladder with rivanol and on cystoscopy failed to find any traces of the candle except for the wick, which I removed with the help of an operation cystoscope (Sass-Wolf). The paraffin-wax had evidently become completely dissolved. The cystitis subsided after three days' treatment by washing the bladder out with rivanol and instilling 100 ml. of silver nitrate (1 in 200). When the patient was asked if he himself had introduced the candle into the urethra, he reluctantly admitted that two days previously, while drunk, he had had intercourse with a prostitute whom he could not pay. She in her anger had inserted the candle while he was asleep.

—I am, etc.,

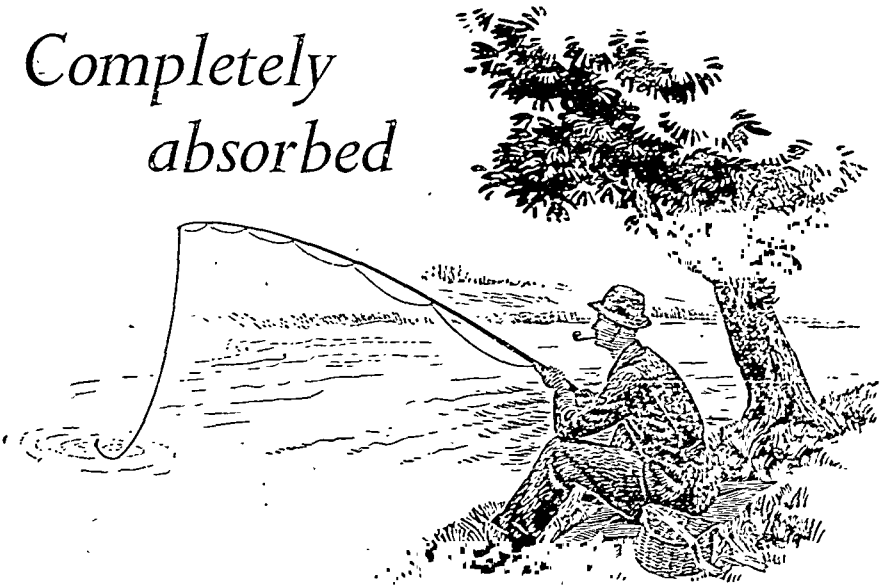
London, S.W.5. B. B. RAPACKI.

Nucleoprotein, Virus, and Mouse Cancers

SIR,—Low-temperature treatment of mouse carcinoma tissue yielded remarkable results in the laboratories of the Imperial Cancer Research Fund (July 30, pp. 251, 253, 255). As to the facts, I hope they will readily obtain ample confirmation; as to the theories attached to them, however, I deem it necessary to consider further possibilities as well. May not very low temperature cause structural changes in the protein molecule itself? I refer particularly to the nucleoproteins of the chromosomes, and this altered molecule might be the causative agent of the tumours. Experimental grounds for this suggestion can be found in the Continental literature. Kanuo Yamafuji and Teigen Cho (*Biochem. Z.*, 1948, **318**, 95) claimed to be able to produce tobacco-mosaic virus by keeping the plant at higher temperatures (43–45° C.) and the polyaeder virus of the silkworm by this and other means. The virus so produced seemed to be to a certain extent transmissible, without any further temperature effect. Their theory is that normal nucleoprotein becomes denaturated nucleoprotein, which becomes polymerized nucleoprotein, which becomes a virus.

Although the authors did not refer to the production of tumours in this article, the possibility cannot be left undiscussed. The following two experiments therefore appear to be necessary. (1) The same cooling procedure should be applied to non-tumour tissues, and these should be grafted into an animal afterwards to ascertain the behaviour of normal tissue protein under such circumstances. (2) Lower temperatures than −79° C. should be applied—say −150 or −200° C.—to prove that there is a low temperature which kills the virus. Without such proof the virus nature is contestable, and the possibility of a non-living agent—i.e., a polymerized molecule—is likely.

It is a puzzling observation by Dr. Mann that it is not the time of freezing but the repetition of it with corresponding thawing that causes a diminution in the infectivity of the agent. It might be that the virus is more easily killed by repeated freezing than by a prolonged spell, but the protein molecule may have the peculiarity of withstanding polymerization, becoming resistant to it on repetition. Regarding the virus, it would be strange if it is killed by the process of thawing when it is resistant to extreme low temperature. It might be equally suggested that the denaturation of some virus-inhibitory substances, the existence of which is propounded by Dr. Mann, does not take place on repeated freezing and thawing. This would be a further field of research. There are many more interesting points. They are, however, beyond the scope of a letter, which should be brought to an end by expressing a high appreciation for the experimental results which give so much food for thought.—I am, etc.,



London, N.W.2. J. KUCHARIK.

B.M.A. Tuberculosis Group

SIR,—May I draw the attention of all old tuberculosis officers, tuberculosis superintendents, and tuberculosis physicians to the newly constituted B.M.A. Tuberculosis Group, and urge all to join it? I hope secretaries of local tuberculosis societies in England, Wales, Scotland, and Northern Ireland will be willing to help, first by getting a supply of forms from B.M.A. House and then by circulating them to their members and having copies available at all the early autumn meetings. If 90% of tuberculosis workers join the group the tuberculosis service will wander less in darkness and confusion than at present.—I am, etc.,

Church Stretton, Salop. G. LISSANT COX.

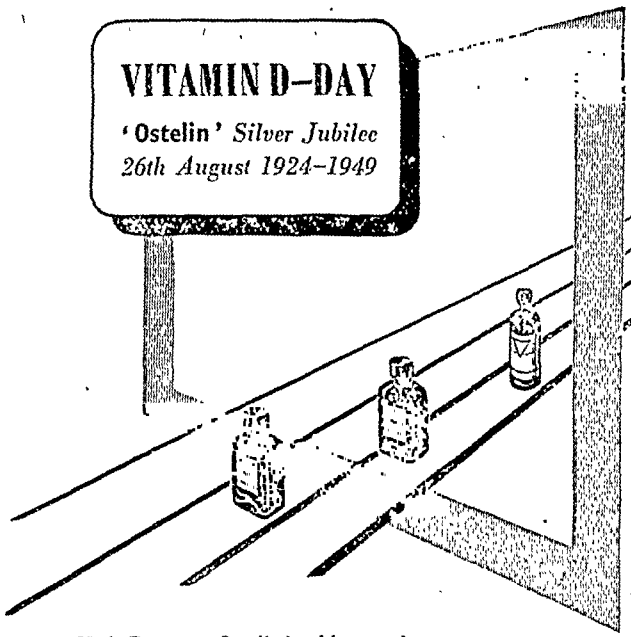
Completely absorbed

Gelatin Sponge A & H, a sterile absorbable hæmostatic, has applications in all branches of surgery, from the simple epistaxis encountered in general practice to the more complex operations of neurosurgery.

It minimizes blood loss when adequate hæmostasis cannot be obtained by ligature, and will help to increase the safety of operative surgery in many fields.

Gelatin Sponge A & H is pliable and may be moulded easily to any shape or size to meet the requirements of the occasion.

Supplied sterile in glass containers in strips 2 cm. × 6 cm. × 0·7 cm., in boxes of six tubes each containing one piece, and thin wafers 2 cm. × 2 cm. × 0·1 cm. in boxes of six tubes each containing 6 pieces.



GELATIN SPONGE A&H

An absorbable hæmostatic

Literature and further particulars will be sent on request.

High Potency 'Ostelin' tablets each contain 50,000 units of vitamin D; ampoules contain 300,000 units of vitamin D per cc.

25 YEARS AGO vitamin D began its clinical progress with the introduction of 'Ostelin' Liquid. First recognised as the specific cure for rickets, vitamin D is now accepted as an essential measured addition to a wide range of nutritional products . . . from milk food to margarine. For the clinician, vitamin D today is gaining new significance with the overwhelming success of High Potency 'Ostelin' in the treatment of lupus vulgaris.

POINTS FROM LETTERS

Histamine Desensitization in Ménière's Disease

Dr. D. A. DRAFFIN (Newcastle-upon-Tyne) writes: Wing Commander Saville Paul (July 23, p. 216) draws attention to an interesting case of Ménière's disease which he treated by histamine desensitization, and he adds that it is reasonable to assume "that a cure has been probably effected." Surely the following errors have been made. (1) The natural history of this type of case has been ignored, for many cases of this type tend to get less frequent attacks in any case. How much improvement in this officer's morale will contribute to mitigation of the tinnitus (which he incidentally still has) is difficult to assess. (2) Faith has been placed in the histamine test. (3) The body has theoretically been desensitized to what is closely related to, if not identical with, the natural substance of the body, on which the body relies to a large extent for its defence against attacks from all sides, be it bacterial toxins, injury, or allergens.

The Elderly Sick

Dr. W. R. E. HARRISON (Buxted, Sussex) writes: Your leading article "*The Elderly Sick*" (Aug. 6, p. 324) might have been more complete had it contained a warning against letting the pendulum swing too far in the direction of over-treatment of the aged. With ever-increasing lay participation in medicine, with "health" visiting, mobile physiotherapy, voluntary car pools, etc., there is, I submit, a grave danger that all sense of proportion may be lost. You speak of co-operation between G.P. and social services, lay-controlled. Do you, I wonder, realize the difficulty in which a G.P. may find himself should he try to do his duty by curbing their exuberant offers of help? As I write, a record harvest stands in stooks exposed to the risk of a break in the weather. A handful of men are struggling to get it in, but the towns and villages are thronged with people doing next to nothing. Let our professors of sociology come down from the sentimental clouds and bend their minds to the treatment of this besetting sin of our sickly civilization. Let our social reformers not make things too difficult for the young and vigorous among our people upon whom depends the bare survival of young and old alike.

Antihistaminic Drugs for Burns

Dr. S. SHUBSACHS (Manchester) writes: While I agree with your correspondent Dr. Donnell Deeny (Aug. 6, p. 336) that it is logical to give an antihistaminic drug in burns, I must point out that the raised temperature is more likely to be due to other conditions, such as sepsis or heatstroke, than histamine excess. It is true that elevation of skin temperature 1° or 2° F. (0.6°–1.2° C.) can occur after the injection of small doses of histamine, as pointed out by Samson Wright (*Applied Physiology*, 1945, p. 556). But major burns are usually associated with normal or subnormal temperature, a rise in temperature only occurring after sepsis has set in. On the other hand, heatstroke can occur with minimal liberation of histamine in the skin. If the use of an antihistamine in burns leads to neglect of the significance of a raised temperature, then tragedies will occur and a valuable aid in the treatment of burns be unfairly discredited.

Tuberculosis in Scotland

Dr. B. C. SAALER (London, N.W.11) writes: May I draw your and Mr. Walter Elliot's attention to a book by Fliess entitled *Vom Leben und vom Tod* (Jena, 1909), which I am afraid has not been translated into English? Discussing the tuberculosis mortality rates for Prussia, he warns the reader not to expect the curve always to move as it would if it depended on external factors only. According to him a nation is a biological unit and its life process is controlled by internal factors. Life is lived in waves; there are "high and low tides," mortality being low at low tides and increasing with the rising tide. He supports these views with evidence derived from knowledge he obtained through the study of the time factor in the life history of generations of human beings, animals, and plants, correlating all major events not due, or due not solely, to external influences. . . . A few questions raised by Mr. Elliot (Aug. 6, p. 297) point indeed to the possibility of an internal factor being responsible for the rise in the curve of the Scottish pulmonary tuberculosis mortality rate. What is affecting Glasgow which is not affecting Birmingham and Cardiff would be easy to see. The inhabitants belong to different biological groups. In England the "slope to the north" would become intelligible, and, as regards the different trend in the more agricultural counties of Northumberland and Cumberland, one could think of a greater reluctance of a peasant population to intermarry with city-bred people in Scotland, who, according to the figures given by Mr. Elliot, are in the main affected by the higher tuberculosis mortality rate. . . .

Obituary

Sir ALAN NEWTON, M.S., F.R.C.S., F.R.A.C.S. F.A.C.S.

Sir Gordon Gordon-Taylor and Professor C. Lambert Rogers write: The moving tributes (Aug. 20, p. 440) to the late Sir Alan Newton leave little for other friends to add, but perhaps further reference may be made to his enduring and passionate desire to promote the science and art of surgery in Australasia, and to ensure that the Cinderella sister college, in the inception and nurture of which he had played so important a role, should in all its activities be not unworthy of the Royal College of Surgeons of England with all its great tradition. Emphasis may be laid on the dignity and decorum on which he insisted in connexion with all the examinations held in the buildings of the Royal Australasian College of Surgeons. As Censor-in-chief he organized and himself superintended a primary fellowship examination in 1934, in which one of us (G. G.-T.) was privileged to participate: nothing was left undone, nothing omitted, nothing unanticipated, so that the examination might be conducted in the best tradition of Queen's Square and Lincoln's Inn Fields. To this end he gave up all his own work for a week and never left the building in Spring Street, Melbourne, during the hours of the examination. With princely courtesy, but with unmistakable firmness, it was impressed on the visitors from the English College of Surgeons that they were in Melbourne to conduct an important examination and not for their own enjoyment, and the mildest *divertissement* in which they might indulge had perforce to be kept from his ears. He would certainly have frowned had he known the late hours at the card-table in the club kept by the distinguished examiner in physiology, although he was well aware that the Royal College of Surgeons of England never had a better ambassador than George Buckmaster. As an examiner himself he was feared but respected.

As long ago as 1945 one of us (L. R.), speaking at the annual meeting of the Royal Australasian College of Surgeons, envisaged a day when there might be an interchange of examiners between the Mother Country and the Commonwealth, a dream that has recently been realized in the active part played by Professor Sunderland in a recent primary examination in London, but the official recognition of the Australasian primary fellowship by the English College, which Sir Alan had for so long regarded as a "statesmanlike desideratum," evoked in his breast the liveliest satisfaction. As alumni of Middlesex Hospital, we are both proud that he too learned anatomy within our walls, and still remember how 30 years ago a tall upright figure in the uniform of a major in the A.I.F. might have been seen striding into the dissecting-room of "Middlesex," along that floor which so many young surgical postgraduates from the lands under the Southern Cross have subsequently trod. As lecturer on surgical anatomy in the University of Melbourne doubtless he taught and retaught those lessons that he had learned as a disciple at the feet of "Tim" Yeates, whom he himself helped to discover and who remains so beloved a figure to Australian visitors of the third and fourth decades of the century.

It is curious that the motto of the Royal Melbourne Hospital which he served with such distinction and loyalty throughout his life should be the selfsame Virgilian line as that proudly possessed by the hospital in London which is our alma mater, and somewhere he himself has written that

"the secret of the care of the sick is to care for the sick." To this end he devoted his life unsparing of himself. Alan Newton was one who walked worthy of the vocation to which he was called, and had that gay, serene spirit which, as Schiller tells us, is the source of all that is noble and good.

Dr. ALBERT HOPKINSON died suddenly at his home in Cambridge on July 31 at the age of 85. The son of John Hopkinson, a former lord mayor of Manchester, he was educated privately and then at Owens College. In 1881 he came up to Emmanuel College, Cambridge, where he took his M.A. and M.B. degrees in 1889. He returned to Manchester and entered into general practice in Withington with the vigour and enthusiasm which were part of him. His especial love was the human aspect of practice, and he devoted himself with kindness, courtesy, and tireless energy to those under his care. It was during this period that he acquired the great human knowledge and sympathy which enabled him to influence the many medical students he taught in the latter part of his life. During the 1914–18 war Dr. Hopkinson was appointed medical officer to the Mosley Road Hospital, Manchester, which was devoted to the treatment of injuries to, and diseases of, the nervous system. "Here," Sir John Stopford wrote, "he worked tirelessly, not only clinically, but in encouraging the men. By his shrewd observation he did much to make possible the early investigations which greatly influenced the subsequent treatment of these diseases. His modesty made it impossible for him to realize the value of the work he was doing, but his colleagues and many of his patients have reason to be very grateful to him." In 1919 Dr. Hopkinson retired and came to live in Cambridge. At the invitation of his old college he undertook the supervision of medical students and became an assistant demonstrator in the school of anatomy, holding this appointment for nearly twenty years. Here he met and helped all the medical students who came to Cambridge during that period. The medical students in the materialistic world of the early 'twenties were apt to feel that they could ill afford the time to listen to his philosophic generalizations, and it was only in later years that they became fully appreciative of the lessons that he had taught them. It was a remarkable achievement to become a competent teacher of anatomy after half a lifetime in general practice, and only the possessor of an unusually retentive memory could have succeeded. In his teaching Hopkinson always made a point of emphasizing the applications of anatomy in practice. Patient and painstaking, he took a keen personal interest in the undergraduates, many of whom kept in touch with him long after they had gone down. Nor did he forget the subjects in the dissecting room, for he wrote a poem, a plea for their reverent handling, which was printed in the *Cambridge Review*. Hopkinson served on the advisory council of the Cambridge University Medical Society until after the recent war. The contact which this gave him with the rising generation of medical students was a constant joy, not only to him but to them. He was a life member of the British Red Cross Society. He also acted as treasurer for the Universities' Mission to Central Africa. As an undergraduate he represented his college at rugby football and athletics, and rowed in the college boat. All his life he was a keen mountaineer, and with his four brothers he was a member of the Alpine Club. In later years he took an especial interest in the Cambridge Mountaineering Club, and a more active one in the University Swimming Club, swimming a mile when he was close on seventy. His family life, despite the loss of one son in the first world war, was a very happy one until the death of his wife ten years ago. He is survived by two daughters and two sons, one of whom is in the medical profession. With the passing of Albert Hopkinson, Cambridge has lost a great and lovable personality who by his example has influenced the lives of many hundreds of medical men practising to-day.

Dr. DOUGLAS BELL died at his home at Skelmanthorpe on July 21 after a short illness. He was educated at the Watson Academy at Edinburgh, and graduated M.B., Ch.B. at Edinburgh University in 1904, taking the D.P.H. three years later. After a short period of assistantships he settled down in general practice with his brother, Dr. William Bell, at Skelmanthorpe, near Huddersfield. During the 1914–18 war he held a temporary commission in the Royal Navy and served in the flagship *H.M.S. King George V* at Jutland. He was for a time medical officer to the Royal Naval Barracks, Chatham. After the war he returned to general practice in Skelmanthorpe and was Medical Officer of Health to the Denby Dale Urban District from 1939 to 1945. He took a keen interest in all local activities; possessed of a strong personality, he was renowned for his forthright manner and his intolerance of petty officialdom. The personal and intimate family history of his patients was an open book to him, and he was an outstanding example of the old type of family doctor giving unstinted service to the community. His practice was his all-absorbing interest. It was his wish to die in harness, and it was fulfilled. He is survived by his wife and his son, Dr. Ian Bell, to whom the sincere sympathy of his colleagues and friends will be extended.

Mr. JOHN ROBERT FOSTER died at Danby on Aug. 5. Born at Sleights, Yorkshire, in 1868, he graduated at Edinburgh University in 1893 and took the F.R.C.S.Ed. in 1901. After holding house appointments at the Central London Ophthalmic Hospital, the Royal Westminster Ophthalmic Hospital, and the Royal National Throat, Nose, and Ear Hospital, Golden Square, he was appointed ophthalmic surgeon to the Hartlepools Hospital. A year later he was appointed ophthalmic surgeon to the Cameron and Howbeck House Hospitals and aural and ophthalmic surgeon to the Hartlepools Education Authority. He was an excellent and careful surgeon, and continued work until the age of 64, when he had to retire from hospital and private practice owing to ill-health. He is survived by a widow and three children, the eldest of whom is ophthalmic surgeon to the General Infirmary at Leeds.

Dr. ALEXANDER GORDON LEGGAT, who had practised in Newbury for nearly 30 years, died at Wellington, New Zealand, on Aug. 8. Dr. Leggat was born in Glasgow, and graduated at Glasgow University in 1905. In the 1914–18 war he served as major in the R.A.M.C. at Gallipoli and was awarded the D.S.O. He was a conscientious and able practitioner, and in 1931 was appointed to the staff of Newbury District Hospital. It was then that he found work most congenial to his taste and capacity, for he was a born administrator and took the greatest interest in the administration of the hospital. He was a firm but popular chairman, and kept order with a tact and humour which owed something to his Scottish origin. He will be greatly missed for his work at the hospital and his other activities. Dr. Leggat died as far from Newbury as it is possible to be on this planet, but near and dear to many of the inhabitants of the town. He survived the death of his wife by six months, and leaves a son and a daughter.

Medico-Legal

OVERDOSE OF NITROUS OXIDE

At an inquest held in Dublin on May 31 the jury found that the death of a woman of 38 was due to anoxaemia and cardiac failure following an overdose of nitrous oxide.

This patient had a septic left thumb which required incision. A woman house-surgeon at the Adelaide Hospital said that she had examined the patient and thought she was fit to be given an anaesthetic. She then noticed that the oxygen cylinder in the anaesthetic machine was empty. She asked one of the nurses to get a cylinder of oxygen and this was connected up; she turned on the nitrous oxide fully and the "oxygen" partially. After a few inspirations she noticed that the patient was becoming slightly blue. She therefore turned off the nitrous oxide and turned on the "oxygen." The cyanosis

became even more marked. She then examined the gas cylinders and found that both contained nitrous oxide. An oxygen cylinder was then put in and artificial respiration started. For two hours everything possible was done to revive the patient. She agreed that, though the cylinders were the same size, nitrous oxide cylinders had a black distinguishing mark and oxygen cylinders black with a white ring round the top. With continued usage the distinguishing white paint did tend to become worn.

A nurse described how she had brought into the theatre what she thought was a cylinder of oxygen. She did not examine the label on the cylinder to see whether it contained oxygen or not. The labels on the cylinders of nitrous oxide and oxygen were similar in size and she had no reason to believe that this cylinder did not contain oxygen. Later one of the medical students noticed that both cylinders in the anaesthetic machine contained nitrous oxide. She agreed that though the labels on the cylinders were of the same size they were of different colours. She had not seen gas cylinders being changed before in the course of her training and she had never been told of the distinguishing marks.

A fourth-year medical student said that he had been in the theatre for about five minutes, helping to apply artificial respiration, before he noticed that both cylinders in the anaesthetic machine contained nitrous oxide. He identified the cylinders by the labels. He did not look particularly at the tops of the cylinders.

The senior anaesthetist at the Adelaide Hospital described the methods of resuscitation employed and said that in her opinion death was due to anoxaemia and cardiac failure. Doctors were taught the importance of distinguishing between the colours of cylinders, but she thought that it would be better if the fittings were so arranged that it would be impossible to connect them up wrongly.

The manager of the firm which supplied the cylinders said that they were painted every two years.

The jury gave a verdict in accordance with the evidence and added a rider expressing the opinion that the Adelaide Hospital was guilty of negligence and that there was contributory negligence on the part of the house-surgeon.

Universities and Colleges

UNIVERSITY OF LONDON

The recognition of the British Postgraduate Medical Federation as a school of the University has been extended in respect of its facilities (*a*) at the Institute of Child Health and (*b*) at the Institute of Ophthalmology for three years and five years respectively in the first instance, from Oct. 1, 1948.

Sir Archibald Gray and Mr. J. B. Hunter have been appointed representatives at the University on the governing body of the British Postgraduate Medical Federation and Dr. Audrey Z. Baker representative on the governing body of Nonsuch County School for Girls, Cheam, Surrey.

A further A. H. Bygott Scholarship for 1949–50 (see *Journal*, Aug. 13, p. 393) has been awarded to Wilfred Charles Turner, M.B., B.S.

The Sir William Dunn Scholarship of the value of £100 for one year, which is awarded annually on the results of the second examination for medical degrees (internal and external) held in March, has been awarded, for 1949, to Charles John Edmonds (University College), who proposes to proceed to the B.Sc. (Special) degree in physiology.

Awards of medical entrance scholarships and exhibitions have been made on the results of the London Inter-Collegiate Scholarships Board examination, as follows: *Medical Scholarship*, Miss M. A. Clark (University College). *Bucknill Scholarship*, D. B. Thomas (University College). *Medical Exhibition*, R. Radford (University College). *Sambrooke Scholarship*, R. Conroy (King's College). *Mrs. George M. Smith Scholarship*, Miss M. Y. K. Armstrong (Royal Free Hospital School of Medicine). *Mabel Sharman-Crawford Scholarship*, Miss K. M. Barber (Royal Free Hospital School of Medicine).

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Aug. 6. [No. 31

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1948 (a)	(b)	(c)	(d)	(e)	1947 (Corresponding Week) (a)	(b)	(c)	(d)	(e)

Rate per 1,000 total births (including stillborn)			23					32		

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

¶ Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Poliomyelitis

In the week ended Aug. 13 notifications in England and Wales were: poliomyelitis 236 (164), polio-encephalitis 18 (22). Figures for the previous week are shown in parentheses.

Counties with multiple cases (poliomyelitis and polio-encephalitis together) were: London 30 (31), Bedford 2 (5), Berkshire 2 (3), Buckingham 2 (1), Cambridge 2 (0), Chester 3 (3), Cornwall 6 (9), Devon 9 (6), Dorset 2 (1), Durham 3 (1), Essex 19 (7), Gloucester 7 (5), Hereford 4 (0), Kent 6 (3), Lancs 23 (12), Leicester 4 (5), Middlesex 10 (15), Norfolk 3 (0), Northampton 2 (0), Northumberland 4 (1), Nottingham 4 (1), Somerset 4 (2), Southampton 13 (9), Stafford 4 (2), Surrey 7 (7), East Sussex 5 (2), West Sussex 4 (2), Warwick 10 (5), Wiltshire 2 (2), Yorks East Riding 2 (2), Yorks West Riding 34 (17), Glamorgan 3 (5), Monmouth 4 (2).

Total notifications in the corresponding week of 1947 were: poliomyelitis 568, polio-encephalitis 56.

Discussion of Table

In *England and Wales* there were decreases in the notifications of measles 583, whooping-cough 229, scarlet fever 191, dysentery 49, and acute pneumonia 43, with an increase in the incidence of acute poliomyelitis 17.

The largest falls in the notifications of measles were Durham 55, Sussex 44, Oxfordshire 42, Gloucestershire 42, and Yorkshire West Riding 41; the largest rise in incidence was Warwickshire 65. Notifications of whooping-cough decreased in Lancashire 52 and Essex 30, but rose in Warwickshire 42. The incidence of scarlet fever decreased in London 46 and in Yorkshire West Riding 36. No appreciable changes were reported in the notifications of diphtheria.

A further 4 cases of dysentery have been reported from the outbreak in Warwickshire, Warwick R.D. No further cases of dysentery have been notified from the outbreak in Buckinghamshire, Amersham R.D. There were 16 notifications of dysentery in Lancashire.

Notifications of food-poisoning numbered 356, an increase of 175 on the previous week. The largest notifications were Lancashire 131: Bury C.B. 43, Farnworth M.B. 43, Lytham St. Anne's M.B. 20; Yorkshire East Riding 54: Kingston-upon-Hull C.B. 54; Yorkshire West Riding 30: Sheffield C.B. 20.

In *Scotland* there were increases in the notifications of dysentery 41, scarlet fever 22, and paratyphoid fever 9. The increase in the incidence of dysentery was mainly contributed by Glasgow, where notifications rose from 14 to 59. Of the 10 cases of paratyphoid 8 were notified in Glasgow.

In *Eire* there were decreases in the notifications of whooping-cough 43, measles 24, and scarlet fever 18. There was an increase of 20 in the notifications of diarrhoea and enteritis in Dublin C.B.

In *Northern Ireland* a decrease of 19 in the notifications of measles was the only notable change in the trends of infectious diseases.

Week Ending August 13

Notifications of infectious diseases in England and Wales during the week included: scarlet fever 689, whooping-cough 1,738, diphtheria 78, measles 3,226, acute pneumonia 227, cerebrospinal fever 26, acute poliomyelitis 236, acute polio-encephalitis 18, dysentery 62, paratyphoid fever 26, typhoid fever 11.

When a death grant is payable under the National Insurance Act the cost of a hospital patient's burial arranged by a hospital management committee or board of governors will be met, up to a maximum of three-fifths of the grant, out of the National Insurance Fund. Formerly the maximum was one-half of the grant.

Medical News

Medical Research Council Travelling Awards

The Medical Research Council announces that it has made the following travelling awards for the academic year 1949–50: *Rockefeller Travelling Fellowships in Medicine.*—Mr. W. J. Atkinson, Mackenzie Mackinnon Research Fellow (Royal College of Surgeons), National Hospital, Queen Square, London; Dr. Ruth E. M. Bowden, Lecturer in Anatomy, Royal Free Hospital School of Medicine, London; Dr. R. Daley, First Assistant, Cardiology Department, St. Thomas's Hospital, London; Dr. J. Dawson, Lecturer in Biochemistry, University of Leeds; Dr. C. E. Lumsden, Senior Lecturer in Pathology, University of Aberdeen; Dr. J. S. Robson, Assistant, Departments of Medicine and Clinical Biochemistry, University of Edinburgh. *Dorothy Temple Cross Research Travelling Fellowships in Tuberculosis.*—Dr. A. J. Robertson, Medical Registrar, Royal Infirmary, Liverpool; Mr. J. D. Wade, Surgical Officer, Welsh National Memorial Association (Sully Chest Centre). *Travelling Scholarships under an exchange arrangement with the Centre National de la Recherche Scientifique in France.*—Dr. E. J. Field, Lecturer in Anatomy, University of Bristol; Miss A. M. N. Sewell, Nuffield Research Unit, Psychological Laboratory, University of Cambridge.

American Committee to Study Rheumatism

Dr. Philip Hench, of the Mayo Clinic, has been appointed chairman of a committee in the U.S.A. to study new methods promising to alleviate rheumatic diseases. The other members are Dr. Walter Bauer, of Boston, Mass., General Hospital; Dr. Granville Bennett, of the University of Illinois School of Medicine; Dr. Jerome W. Conn, of the University of Michigan; Dr. W. Paul Holbrook, of Tucson, Arizona; Dr. Robert Loeb, of New York; Dr. Fred Moore, of the University of Southern California School of Medicine; Dr. Jane A. Russell, of Yale University School of Medicine; Dr. Emil L. Smith, of the University of Utah School of Medicine; and Dr. Alfred L. Wilds, professor of chemistry, University of Wisconsin.

New Journal for Radiologists

The first issue of the *Journal of the Faculty of Radiologists* has just been published. All branches of radiology have expanded so rapidly in recent years that the Faculty of Radiologists felt that the time was opportune for the publication of a journal devoted to clinical radiology. This first issue includes a number of papers on cerebral tumour which were read at the annual meeting of the Faculty, and there are also articles on pneumoconiosis, on the radiotherapy of leukaemia, and on the doctor–patient relationship in the treatment of cancer. Inquiries should be addressed to the editor at the Faculty of Radiologists, 45, Lincoln's Inn Fields, London, W.C.2.

Bristol Hospitals Fund

Since July 4, 1948, the Bristol Hospitals Fund has allocated £7,495 to hospital amenities funds, medical charities, and for medical research.

Statistics in Israel

A new publication entited the *Statistical Bulletin of Israel* has been issued by the Israel Central Bureau of Statistics. Various statistics are given for cases of infectious diseases; the figures are fairly complete for the years 1936 to 1947, and figures for the Jewish population are given for 1948 in most cases.

National Association for the Prevention of Tuberculosis

A scholarship of £300 offered by the association to enable a matron from a British sanatorium to spend three months visiting tuberculosis institutions in Canada has been awarded to Miss Nora Burrows, matron of Baguley Sanatorium, near Manchester. It is hoped that a matron from a Canadian sanatorium will pay a similar visit to this country.

Menopausal Syndrome

'Estigyn' enables the symptoms of the menopause, due to decline in the œstrogen secretion of the ovary, to be effectively treated by specific replacement therapy.

'Estigyn' is a highly potent œstrogen derived from natural sources and is active orally. In addition it is non-toxic in therapeutic doses. The improvement in subjective symptoms and the restoration to normal outlook is, in many cases, gratifyingly rapid while at the same time the possible onset of pruritus vulvæ or kraurosis vulvæ is prevented.

ETHINYL ŒSTRADIOL

B.D.H.

'ESTIGYN'

THE INTRAVAGINAL TAMPON IN MENSTRUAL HYGIENE

An important clinical study

Significant facts obtained by the close observation of 25 parous and nonparous women

In view of the increasing use of the intravaginal tampon for the absorption of the menstrual flow, the following important study was undertaken to determine whether or not this method of sanitary control is safe and not prejudicial to health.

Twenty-five women—parous and nonparous—were selected and were under daily institutional observation during two successive catamenial periods. Ranging in age from twenty-one to forty-five, some had previously used tampons, others had not.

The following summary indicates clearly the findings of the study.

1. In not a single instance was there any evidence of local irritation brought about by the use of the tampons.

Reprinted from the Medical Record, U.S.A. for May, 1942

2. No uterine cramps, suggestive of block of the uterine flow or damming back into the tubes were reported in any case of this series.
3. No bladder irritation was reported.
4. The average number of tampons used in a period was ten.
5. In cases in which a cervical erosion was present, neither the amount of bleeding nor the character of the erosion was altered by the use of the tampons.
6. There was no appreciable difference in the bacterial flora of the vagina and cervix, as determined by smear and culture, before menstruation and after the use of the tampons during the menstrual period.
7. There was no appreciable difference in the pH of the vaginal or cervical secretions before menstruation and after the use of the tampons during the period.
8. Absolute comfort and complete absorption of the flow was obtained by the proper correlation of the size of the tampon with the length and calibre of the vagina.
9. *The evidence is conclusive that the tampon method of menstrual hygiene is safe, comfortable and not prejudicial to health.*

TAMPAX

If you are not acquainted with Tampax, descriptive literature and samples of both absorbency sizes will gladly be sent on request.

MEDICAL INQUIRIES: TAMPAX LTD., 110 JERMYN ST., S.W.1

HANDS AND THE MAN . . . No. 8

Mr. . . . . , Specialist in E.N.T. Surgery

The skill with which the surgeon handles his materials must be matched by the skill with which these are made. Behind Ethicon Mersutures is a Research Organisation ever alert to meet latest techniques in surgery by providing appropriate sutures. Every suture and ligature which leaves the famous Mersons factory is tested by the Quality Control Department to more stringent limits than those required by the official standard.

All orders for Ethicon and Ethicon Mersutures should be sent to your usual wholesaler.

MERSONS (SUTURES) LTD.,
BANKHEAD AVENUE, SIGHTHILL, EDINBURGH, 11.

Visits Abroad of Ophthalmologists

During May nineteen ophthalmologists went to Italy on a tour organized by the Faculty of Ophthalmologists. At Pavia the rector of the university received them, and Professor Bietti gave some interesting talks and performed some operations. At Genoa Professor Maggiore showed the party round, and demonstrated some new instruments and some experiments in colour vision. The party then visited Professor Alajmo's clinic at Florence, where they saw some operations performed, including sclerectomy for glaucoma. Next day they went to Rome, where Professor Cavara showed some interesting cases, including one of "crocodile tears," and a hydatid cyst causing retinal detachment. Professor Leonardi in another hospital demonstrated cases of cataract extraction by suction apparatus. On reaching Naples the party was entertained by Professor Lo Cascio, who performed nine cataract extractions in 45 minutes. Finally the party went to Bologna and visited Professor Di Marzio's clinic, where papers were read on pituitary tumours and nasal infection in eye diseases. In June twenty members of the Faculty, under the leadership of Mr. W. Muirhead (Sheffield), were received by the heads of the ophthalmic clinics at Copenhagen, Lund, Uppsala, Stockholm, Oslo, and Gothenburg. Lectures, clinical demonstrations, and operative sessions were arranged, and the tourists were made welcome in the homes of their Scandinavian friends.

Hospital Contributory Schemes

A history of the British Hospitals Contributory Schemes Association will be published in the autumn under the title *Pennies for Health*. The cost will be 13s. 3d. post free, and orders may be sent to the British Hospitals Contributory Schemes Association (1948), Royal London House, Queen Charlotte Street, Bristol, 1.

Faculty of Radiologists

At the recent annual general meeting of the Faculty of Radiologists the following officers were appointed for 1949–50. President: Professor B. W. Windeyer, London. Vice-presidents: Dr. J. L. A. Grout, Sheffield (Diagnosis); Dr. J. R. Nuttall, Leeds (Therapy). Warden of the Fellowship: Dr. S. Cochrane Shanks, London. Editor: Dr. Peter Kerley, London. Hon. treasurer: Dr. J. W. McLaren, London. Hon. secretary: Dr. E. Rohan Williams, London.

Nuffield Orthopaedic Centre

Lord Nuffield has made a further gift to the Nuffield Orthopaedic Centre at Oxford. The donation is of £50,000, and the fund will be used mainly to offer special facilities for visiting orthopaedic specialists and students from the Commonwealth. The gift is comparable to Lord Nuffield's recent benefaction to the Royal College of Surgeons of England.

Medical Films

The following medical films are available on request from the Documentary Film Unit, May & Baker, Ltd., Dagenham: "Thiopentone Sodium and its Use in Intravenous Anaesthesia" (made in co-operation with the Department of Anaesthetics, Westminster Hospital, London); running time is 38 minutes on 16 mm. and 35 mm. (with sound track). "Medical Applications of Sulphonamides"; running time is 34 minutes on 16 mm. and 35 mm. (with sound track). Both films are divided into three sections—namely Introduction (chemistry), Pharmacology, and Clinical Use. Applicants should specify alternative dates when possible. Synopses may also be obtained.

Wills

Professor Stuart McDonald, who was emeritus professor of pathology in Durham University, left £7,933. Dr. Lionel James Picton, of Holmes Chapel, Cheshire, left £15,308. Mr. Robert Leslie Dodds, of London, N.W., left £2,195. Dr. Howard Bluntisham Hodson, of Colchester, left £8,596. Dr. Oswald Hanson Isard, of Tonbridge, Kent, left £59,739, including £100 to the Royal Medical Benevolent Fund.

COMING EVENTS

South-east Metropolitan Regional Tuberculosis Society

A meeting of the South-east Metropolitan Regional Tuberculosis Society will be held at B.M.A. House, Tavistock Square, London, W.C., on Saturday, Sept. 10, at 10.30 a.m., when a lecture on "The Secondary Effects of Tuberculous Mediastinal Lymphadenitis, with Special Reference to Disease of the Middle Lobe" will be delivered by Mr. R. C. Brock. The meeting will be followed by the annual luncheon of the society at Russell Hotel, Russell Square, London, W.C.

Rehabilitation Clinic

A special clinic on rehabilitation will be held by Dr. Howard Rusk, of New York, at the Royal Free Hospital, Gray's Inn Road, London, W.C., on Wednesday, Sept. 14, at 2.30 p.m., when Dr. Rusk will demonstrate his special methods of approach to the subject. The chair will be taken by Lord Horder. Anyone who wishes to be present should notify the Medical Rehabilitation Unit at the hospital.

Association of Army Psychiatrists

The seventh reunion of army psychiatrists will take place at Slater's Restaurant, 18–24, High Street, Kensington, London, W., on Saturday, Sept. 24, from 7.30 to 10.30 p.m. Particulars may be obtained from the honorary secretary, Dr. J. C. Penton, The Old Farm House, 1, Gatehill Road, Northwood, Middlesex.

Lectures in Social Studies

The Institute for the Scientific Treatment of Delinquency (8, Bourdon Street, Davies Street, London, W.1) announces the following university extension lectures for candidates for the Diploma in Social Studies. Twelve lectures on "Criminology," by Mr. H. Mannheim, on Tuesdays, at 6.30 p.m., beginning on Sept. 27; 24 lectures on "Social Philosophy," by Mr. J. J. Hartland-Swann, Ph.D., on Wednesdays, at 6.30 p.m., beginning on Sept. 28; 24 lectures on "Social Psychology," by Mr. R. Elias, Dr.Phil., on Thursdays, at 6.30 p.m., beginning on Sept. 29; 24 lectures on "Social Structure," by Mr. B. C. Adams, on Fridays, at 6.30 p.m., beginning on Sept. 30; 12 lectures on "The Psychology of Delinquency," by Dr. Edward Glover, on Tuesdays, at 6.30 p.m., beginning on Jan. 10, 1950. The lectures are open to members and non-members of the institute and to diploma and non-diploma students. As each class will be limited in number early application for enrolment forms should be made to the education secretary of the institute at the above address. The fee for 24 lectures is £1 10s., and for 12 lectures 15s.

French Medical Congress

The Association des Médecins de Langue Française will hold a congress at Geneva on Sept. 29–Oct. 1. Subjects to be discussed include plasma proteins, hyperthyroidism, and hormone treatment of cancer. Information may be obtained from Professor E. Martin, 16, Boulevard Helvétique, Geneva.

Course on Rheumatic Diseases

A concentrated week-end course on the rheumatic diseases, with lectures, ward-rounds, and practical demonstrations, will be given at the Rheumatism Unit, St. Stephen's Hospital, London, S.W., on Oct. 1 and 2. The course will be opened by Sir Ernest Rock Carling with an address on "Some Social and Economic Aspects of the Chronic Rheumatic Diseases." Other lecturers will include, Dr. Francis Bach, Dr. Grace Batten, Dr. Philip Ellman, Mr. Timbrell Fisher, Dr. Jackson Richmond, Dr. David Shaw, Dr. A. G. Signy, and Dr. Worster-Drought. Applications to attend the course should be made to the medical registrar, Rheumatism Unit, St. Stephen's Hospital, London, S.W.10, or to the Fellowship of Postgraduate Medicine, 1, Wimpole Street, London, W.1.

Safety in Chemical Works

The Association of British Chemical Manufacturers has arranged to hold a conference on "Safety in Chemical Works" on Oct. 7 to 9 at Scarborough.

French Dental Congress

The annual congress of the Confédération Nationale des Syndicats Dentaires will be held on Oct. 3–9 in Paris. Visitors from abroad are invited, and further information may be obtained from the secretary of the congress at 31, Rue Tronchet, Paris, 8e.

International Society of Medical Hydrology

The annual meeting of the International Society of Medical Hydrology will be held at Dax, Landes, France, from Oct. 9 to 15. Further particulars may be obtained on application to the honorary secretary, Dr. Donald Wilson, "Cranbourne," Southdown Road, Bognor Regis, Sussex.

SOCIETIES AND LECTURES

Monday

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At Anatomy Lecture Theatre, Edinburgh University, Aug. 29, 4.30 p.m., "*Influenza in Perspective*," by Dr. C. H. Andrewes, F.R.S.

APPOINTMENTS

MACDOUGALL, IVOR ANDERSON, M.B.E., M.R.C.S., L.R.C.P., D.P.H., Medical Officer of Health and School Medical Officer to the County Borough of Bournemouth. (*From Feb. 26, 1950.*)

PRIESTMAN, AUSTIN, M.B., Ch.B., D.P.H., Temporary Medical Officer of Health, Borough of Richmond and Rural Districts of Richmond, Croft, and Startforth, Yorkshire.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Galewski.—On August 11, 1949, at Queen Charlotte Maternity Hospital, London, to Anna (née Galin), wife of Dr. Galewski, a daughter.

Rosenvinge.—On August 5, 1949, at Carlton Lodge, Harrogate, to Margaret (née Ogden), wife of Dr. Gerald O. Rosenvinge, of 35, Hookstone Drive, Harrogate, a brother for Louise and Stephen—Henry Paul.

MARRIAGE

Marciniec—Macfarlane.—On August 13, 1949, in London, Antoni Marciniec, Captain P.R.C., to Laura Helen Macfarlane, M.D., D.O.M.S.

DEATHS

Blampied.—On August 15, 1949, at Seymour Cottage, La Rocque, Jersey, Harold John Blampied, M.B., B.S., aged 56.

Chissell.—On August 15, 1949, at Middlesex Hospital, Gordon Frank Chissell, M.R.C.S., L.R.C.P., aged 53.

Gater.—On August 10, 1949, at Brighton, Horace James Gater, L.M.S.S.A., of Santos, Little Crescent, Rottingdean, Sussex, formerly of Peckham.

Green.—On August 19, 1949, Philip Withers Green M.R.C.S., L.R.C.P., of 5, Cheyne Gardens, Chelsea, London, S.W.

Hollings.—On August 13, 1949, Guy Bertram Hollings, M.D., F.R.C.S.Ed., of Torrington House, Berkhamsted, Herts.

Jackson-Taylor.—On August 18, 1949, Basil John Francis Jackson-Taylor, M.R.C.S., L.R.C.P.

Jameson.—On August 20, 1949, at 95, Bouverie Road, Folkestone, Archibald Douglas Jameson, M.R.C.S., L.R.C.P., Lieutenant-Colonel, R.A.M.C., Ret., aged 71.

Laidlaw.—On August 9, 1949, at 109, Grantchester Meadows, Cambridge, Janet Young Laidlaw, M.B., B.S., aged 66.

Leggat.—On August 8, 1949, at Wellington, New Zealand, Alexander Gordon Leggat, D.S.O., T.D., M.B., Ch.B., D.P.H., of Monkswood, Newbury.

Littlewood.—On August 1, 1949, at "Highfields," Woodhouse Road, Mansfield, Samuel Littlewood, M.B., B.S., aged 64.

Lyle.—On August 2, 1949, at "Moyle," Belmont Road, Belfast, William Lyle, M.B., B.Ch., B.A.O., M.P., aged 78.

Newfield.—On August 13, 1949, at Buck's House, Great Bardfield, Essex, Maurice Newfield, M.R.C.S., L.R.C.P., aged 55.

Owen.—On August 19, 1949, at Royal White Hart Hotel, Beaconsfield, Daniel Stanley Owen, L.S.A., late of Langford House, Higham Hill, Walthamstow, London, E.

Paterson.—On August 2, 1949, George William Murray Paterson, F.R.C.S.Ed., of 84, Oswald Road, Scunthorpe, Lincs.

Ramsay.—On July 26, 1949, at Edinburgh, James McAlister Ramsay, L.R.C.P &S.Ed., L.R.F.P.S.Glas., of 11, Brucehaven Crescent, Limekilns, Fife.

Scott.—On August 16, 1949, at Hill Crest, Sileby, Leics, Alexander Scott, M.B., Ch.B.

Steven.—On August 9, 1949, at "Ardglass," Lochgoilhead, George Henry Steven, M.B., Ch.B.

Stone.—On August 17, 1949, at Sedgewood, Vittoria Walk, Cheltenham, Charles Ainslie Stone, M.B., B.Ch., aged 70.

Symons.—On August 18, 1949, at 17, Boscombe Spa Road, Bournemouth, Annie Dorothea Symons, M.R.C.S., L.R.C.P.

Warwick.—On August 21, 1949, at the Middlesex Hospital, London, W., William Turner Warwick, F.R.C.S., of Fitzroy Farm Cottage, Highgate, London, N.

White.—On August 4, 1949, in Guernsey, Digby Cooke White, M.D., aged 81.

Whitelaw.—On August 14, 1949, at Osborne House, Bathampton, Bath, James Charles Graham Whitelaw, M.B., B.Chir., aged 43.

Willoughby.—On August 13, 1949, at St. Bartholomew's Hospital, London, William George Willoughby, M.D., of 17, Hartfield Square, Eastbourne, aged 83.

Wills.—On July 30, 1949, at Bath, James Tremlett Wills, M.B., B.Ch., aged 78.

Any Questions ?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Hypertension and Pregnancy

Q.—*A married woman aged 26 is anxious to have another child if it is not likely to damage her health. During her first pregnancy, which ended in a live birth, she suffered from high blood pressure. In the 32nd week of her second pregnancy her blood pressure was 145/95 mm. Hg; there was oedema of the ankles but no albuminuria. At the 36th week she went into labour and was delivered of a stillborn child weighing 3 lb. (1,360 g.) and an unhealthy, small, infarcted placenta. There were no foetal abnormalities. Her blood pressure is now 135/85 mm., and there is no albuminuria. What advice should I give her about another pregnancy?*

A.—The history suggests a diagnosis of essential hypertension rather than a recurrent pre-eclamptic state, and this despite the fact that the blood pressure is not much raised at present. Is there any family history of vascular disease? If this diagnosis is correct, it seems likely that another pregnancy will also be complicated by an exacerbation of the hypertension and possibly by albuminuria in the later weeks. In such event there is also an appreciable chance that the woman might be left with a persistently raised blood pressure. Although it is not inevitable, the next foetus is likely to be poorly developed, and its live birth could not be guaranteed. These points should be put to the patient, but it is doubtful whether the risks are grave enough to justify advising her not to embark on another pregnancy. It would, however, be wise for her not to try to conceive until two years after the last confinement, and at that time estimations of blood pressure and renal function should be made. During the next pregnancy she should rest for regular periods each day and should be kept under the closest observation. A rise in blood pressure or the appearance of albumin in the urine would call for her admission to a well-equipped maternity hospital, and in the interest of both mother and child premature termination of pregnancy might be necessary. The method of termination could be decided according to the circumstances present at the time, but caesarean section under local analgesia has its place in some of these cases.

Blood Circulation Time

Q.—*The fact that sodium dehydrocholate, when injected intravenously, gives rise to a bitter taste on the tongue has been utilized to determine the arm–tongue circulation time of the blood. The interval between the injection into a vein of the arm and the moment a bitter taste is experienced is generally reckoned to be from eleven to nineteen seconds. Over a similar distance—from a vein in the antecubital fossa to the olfactory nerve—by using a solution of sodium penicillin I have lately demonstrated a circulation time of eight seconds or less. Perhaps this is because the olfactory sense organ is more quickly stimulated. I should like to know wherein lies the flaw, as the figure arrived at by this method is only about half that generally accepted.*

A.—Determination of the circulation time, usually measured from the arm to the tongue, is a very complex affair. A high concentration of sodium dehydrocholate is produced in the veins of the arm into which the injection is made. This concentration, however, is considerably diluted in the great veins and in the right heart. Furthermore, rates of blood-flow through the different parts of the lung vary somewhat, and by the time the systemic arteries are reached the injected substance has been considerably diluted. The concentration in arterial blood begins to rise about the 9th to 12th second after injection, reaches a peak in 14 seconds, and thereafter

falls away more slowly. These phenomena have recently been well demonstrated by Prinzmetal and his colleagues (*J. Amer. med. Ass.*, 1949, 139, 617) by following the passage of injected radioactive sodium through the right and left heart with a Geiger counter placed over the chest.

It is clear that sensory perception of the arrival of these diluted test substances is governed by the sensitivity of the sensory end-organs and by the reaction-time of the patient. Presumably the olfactory perception of sodium penicillin is sensitive to much greater dilutions of the substance, and the very beginning of a rising concentration may be recognized. Sodium dehydrocholate is recognized only some seconds later when a greater concentration reaches the taste buds in the tongue. Alternatively, substances perceived by sense of smell may diffuse through the lungs, reaching the nose in the expired air. This is the basis of the arm-lung circulation time with injected ether, which is, of course, much shorter than the arm-tongue time. Some of the prolongations of circulation time in heart failure are due to dilution of the test substance in the dilated heart and engorged lungs. The patient simply does not perceive the smaller concentrations reaching his tongue until the delayed peak of concentration is attained, after which the taste may last an unduly long time. Rapid injection of the test substance is of the utmost technical importance if any comparative value is to be placed on circulation times for clinical assessment.

Jealousy in a Child

Q.—*I am the mother of two little boys. The elder, Peter, aged 4, is intensely jealous of the younger, Paul, aged 2½. The jealousy first appeared when Paul started to toddle and Peter constantly pushed him over. Now he hits him, teases him, refuses to let visitors speak to him, interrupts plans for little outings, etc., and screams and rages for anything that Paul is playing with. Paul in his early days was cared for mainly by my mother's help, as I was temporarily crippled and could not handle him. I tried to show Peter how much I loved him, and had him with me a good deal, but in order to achieve safety and peace for Paul I have often had to smack him. Paul is a shy, good-tempered, generous little boy. Peter gets on very well with other people and seems to have a charming personality, and I do want to help him to grow up well balanced. This temperament has appeared in older generations of the family, so I feel that it may be an inborn tendency rather than something that has arisen as a result of environment only. I would appreciate it if you could indicate a steady line of action.*

A.—The origin of Peter's extreme jealousy of Paul may well be connected with your prolonged disability. Although this had nothing to do with the latter's birth, it would certainly have appeared to the eighteen-months-old Paul as the work of the wicked baby who had damaged you and might do so again. It is quite possible that the word "jealousy" is out of place in this case, for, since the attacks on Paul did not start for about a year, it may be that Peter really wanted to like the new brother, and could do so as long as his inability to get about made him harmless. At the toddling stage, however, Paul's increased mobility would again make him appear as a danger against which you must be protected at all costs by the loyal Peter, who would then have been 2½ years old—a peak period in a child's attachment to his mother. This explanation, being in line with common fantasies of early childhood, is more likely to account for the trouble than can any theory of inborn tendency, especially as Peter has a charming personality otherwise. He is now at an age when companionship with his father might help by leading to adoption of the latter's attitude—"being like Daddy" towards Paul and yourself. Another suggestion is to tell Peter quite factually how your disability arose, making it clear that it had nothing to do with Paul. This might be followed by schemes in which you and he in partnership arrange things for Paul, so making him feel you are on his side, though obviously you must protect the younger son until there is a change of attitude, and this may take much time and patience. If these home measures do not succeed, as they may well do, it is likely that a fairly short period of child psychotherapy would be effective.

Mild Thyrotoxicosis

Q.—*In a mild case of primary thyrotoxicosis in a female aged 30 there appear to be three ways of treatment: (1) with Lugol's iodine; (2) with methyl thiouracil; and (3) by subtotal thyroidectomy. Some cases are effectively controlled by Lugol's iodine continued indefinitely; if this treatment is not enough, can it be supplemented with methyl thiouracil? What is the current relationship between medical and surgical treatment of mild early cases in patients under 30?*

A.—Most authorities would contest the statement that thyrotoxicosis can be controlled indefinitely by Lugol's solution. It is common experience that iodine has a rapid and short-lived effect, which reaches a maximum about three weeks after its administration is started. The available effective methods of treatment are with methyl thiouracil, by operation, and with methyl thiouracil followed by operation. In a mild case in a young woman, prolonged treatment with methyl thiouracil in small doses is a reasonable choice. At this age the disease is often self-limiting, and after nine to twelve months it may be possible to withdraw the drug without consequent relapse. Operation is to be preferred if there is a large goitre, and particularly if it has a retrosternal prolongation, for it may increase in size after medication with thiouracil. Many prefer preliminary "detoxication" with thiouracil, followed by thyroidectomy. An interval of three weeks should elapse between discontinuing the drug and the operation, and during this period Lugol's solution should be given. By this step the vascularity of the gland is decreased and the technical difficulties of the operation are lessened. It cannot yet be said that the relative positions of surgery and methyl thiouracil in the treatment of thyrotoxicosis have been precisely defined.

Acroparaesthesia

Q.—*A woman aged 44 has for three years complained of paraesthesia in the tips of her fingers, worse on the left than the right, and followed by a pain which spreads up the arms to the shoulders. These symptoms start when she gets warm in bed; the pain is worst after a day's washing. There are no abnormal physical signs: radial pulses are equal in rate and volume; sensation and reflexes are normal; there is no tenderness over the ulnar nerve; and the skin is normal in appearance. Please suggest diagnosis and treatment.*

A.—The condition as described is acroparaesthesia, which is fully discussed in textbooks. No physical signs are found when tingling is not present, but the hand is often red and puffy then. The condition is vascular, and is thought to be the same as release tingling.

Excessive Salivation

Q.—*In a female aged 56 suffering from progressive motor neurone disease the most distressing symptom is loss of control of salivation; the saliva pours from her mouth in a constant stream. The following drugs have had little or no effect: tincture of belladonna, stramonium, hyoscine, tincture of opium, and nicotinic acid. Can anything else be done to control the salivation?*

A.—This symptom is a very difficult one to treat, because in most cases it is the failure of the patient to control the salivation which causes the trouble. We do not know of any other substance which can be used, but atropine alone, if given in large enough doses, is sure to reduce salivation.

Sulphonamide Sensitivity

Q.—*A woman died of subacute necrosis of the liver as a result of sensitivity to sulphonamides. Is sensitivity to these drugs an inheritable factor, and is there a simple cutaneous test to determine such sensitivity?*

A.—There is no satisfactory skin test to determine sulphonamide sensitivity. Such sensitivity is not known to be inherited, and subacute necrosis of the liver, although sometimes attributed to the action of one of the sulphonamide drugs, is a rare and unusual sequel to their administration.

Alopecia Totalis

Q.—*Eighteen months ago a healthy woman aged 35 observed a small bald patch behind the ear. In spite of treatment the condition spread to involve the occiput and rapidly progressed to alopecia totalis; a few lanugo hairs are visible on the body, but no pubic or axillary hair, eyelashes, or eyebrows exist. The patient continues to menstruate normally and her weight remains constant. The scalp has been painted with a preparation containing radon as well as with liquor iodi fortis, and the patient has been given injections of testosterone propionate, but all to no avail. Is the prognosis quite hopeless so far as regeneration of scalp hair is concerned?*

A.—The alopecia is, of course, symptomatic and there must be some underlying cause, probably psychogenic or endocrine, even though it is not apparent. It is important to know whether the patient had previously suffered from alopecia or whether there is any family history of the affection. Prognosis depends on the underlying cause. There is probably no destruction of follicles, so that theoretically hair may regrow, but in practice the prognosis is generally bad.

Infection from Crockery

Q.—*Can you tell me if the use of glazed earthenware vessels may be detrimental to health owing to frequent crazing or fine cracking of the glaze allowing the entry of organisms? What is the risk in Britain, as compared with countries in the East?*

A.—Chipped and cracked cups, which are consequently impossible to clean, can convey bacteria from mouth to mouth and may therefore be concerned in transmitting throat and mouth infections, such as streptococcal sore throat and Vincent's angina; they have even been known to transmit syphilis. This does not apply to utensils used only in the kitchen, since there is no reason why they should become contaminated with pathogenic bacteria. The worst that bacteria in cracks in earthenware glaze are likely to do in ordinary circumstances is to cause the more rapid souring of milk. The same considerations would seem to apply in any country, except that in hot climates and without refrigeration bacterial growth would be more rapid.

Chronic Intermittent Priapism

Q.—*A man of 42 recently suffered for a few days from pain in the groin, with maximum tenderness over the right pubic bone where the cord passes over it. There was no abnormality of the cord and no rupture; both testes were descended and not swollen or painful. There was, however, a partial erection of the penis, which was painful from congestion, and a small hard lump was palpable underneath at the root of the organ. The patient had been circumcised, but gave a history of penile eczema from infancy to the age of 25. The skin of the penis, though intact, is easily irritated by slight trauma. There have been occasional similar attacks for a year or two. His sexual life seems to be normal. Can you suggest any treatment?*

A.—Persistent erection of the penis occurs with thrombosis of the corpora cavernosa, which may be of unknown causation or associated with various disorders of the blood; it is a well-recognized complication of chronic myeloid leukaemia. Although the congestion of the organ raises suspicions of a thrombotic origin, the recurrent attacks make it improbable. A chronic intermittent priapism is known to occur; it is sometimes associated with lesions in the posterior urethra or prostate or with disease of the central nervous system. These aspects of the case require investigation. No cause can be found in other instances, and treatment is then unsatisfactory. Some relief has been obtained with heat applied by the diathermy current, and occasionally irradiation is effective. The palpable nodule at the root of the penis raises the possibility of fibrous cavernositis or plastic induration of the penis. Priapism is not a usual symptom in this condition, which is again resistant to treatment, although some success has followed injections of fibrolysin into the lesions.

Sodium Glutamate

Q.—*What are the chemical and physical properties, physiological actions, method of manufacture, etc., of sodium glutamate?*

A.—Sodium glutamate is the sodium salt of glutamic acid—a simple amino-acid which occurs in food protein and as part of the molecule of folic acid. Its structure may be thought of as a compound of acetic acid and the amino-acid alanine. Alanine is $H\text{–}CH_2.CH.NH_2.COOH$, while acetic acid is $H\text{–}CH_2.COOH$. If H is removed from each substance and the residues are joined, the result is glutamic acid. Like other amino-acids, it has no physiological action. Its manufacture is indicated by the structure.

NOTES AND COMMENTS

Delirium Tremens.—Dr. A. E. CARVER (Nuneaton) writes: I was shocked to read in answer to the question, "What is the best treatment for delirium tremens?" ("Any Questions?" July 23, p. 242), that small doses of alcohol plus intramuscular injections of 2 dr. (8 g.) of paraldehyde were recommended. Although D.T. is not now so common as it used to be in my young days, I did think that there was general agreement among those called upon to deal with it that once it was established alcohol should be immediately and completely cut off, since its exhibition has been found to prolong this brief psychosis. In long-standing topers, who alone are subject to D.T., a small quantity of alcohol is irritating, not soothing. Forty and more years ago there was an idea that D.T. was due to an excess of some hypothetical anti-alcohol substance in the body and that giving alcohol would neutralize this, but such an idea has long since been disproved. Healthy heavy drinkers sent to prison and abruptly cut off alcohol do not develop D.T. Some trauma or acute disease (e.g., broken leg or pneumonia) seems to be a necessary precipitating factor, and the welfare of the patient depends far more upon how this is attended to than upon the restless delirium, which usually is controllable by repeated small injections of hyoscine hydrobromide. Other sedatives and hot packs may also be employed, but intramuscular injections of paraldehyde should certainly be eschewed. I wonder whether he who answers the question has tried them.

Sulphur-containing Sweat.—Dr. J. N. MORRIS (Stoke, Plymouth) writes: In "Any Questions?" (July 16, p. 189) sulphur-containing sweat is discussed. I have known this condition to follow the taking of Epsom salts or other sulphur-containing laxatives. This may be the explanation in your correspondent's case.

Miss W. JOAN WADGE, F.R.C.S. (London, W.), writes: With reference to the question and answer under this heading ("Any Questions?" July 16, p. 189), I have seen this in patients who were applying a sulphur-containing liniment to the skin (elsewhere than on the hands). Bowel function was normal.

Bee-stings.—Dr. W. K. WENNER (Upper Montclair, New Jersey) writes: With regard to the question on bee-stings in the *Journal* (June 11, p. 1061), may I draw your attention to a paper by W. T. Strauss (*J. Amer. med. Ass.*, 1949, **140**, 603), who reports good results by topical application of the antihistamine "thephorin" (2-methyl-9-phenyl-2,3,4,9-tetrahydro-1-pyridindene hydrogen tartrate)?

Anaesthetics for Domiciliary Midwifery.—Dr. S. RANSOM (Obstetric Unit, University College Hospital, London, W.C.) writes: I am glad that Dr. J. E. M. Barnes (Aug. 6, p. 346) has drawn attention to the misleading statement that the Cyprane inhaler can produce anaesthesia. We in this department at any rate have not been able to use the apparatus for this purpose, though we found it satisfactory for producing analgesia.

SUPPLEMENT TO THE

BRITISH MEDICAL JOURNAL

LONDON SATURDAY AUGUST 27 1949

British Medical Association

REPORT OF GENERAL MEDICAL SERVICES COMMITTEE, 1948

Chairman

Dr. S. Wand was appointed Chairman for the session 1948–9.

Dr. E. A. Gregg

The Committee takes this opportunity of placing on record its appreciation of the services of Dr. E. A. Gregg as Chairman of the Insurance Acts Committee for many years, and of his unfailing devotion to the interests of general medical practitioners.

Obituary

The Committee regrets to report the deaths of Dr. J. W. Bone (Luton), Dr. E. Lewis Lilley (Leicester), Dr. L. J. Picton (Holmes Chapel, Cheshire), and Dr. J. W. Leach (Beauly, Inverness), all of whom were members of the Insurance Acts Committee for many years.

Dr. Bone will be remembered for his valuable services as Treasurer of the National Insurance Defence Trust, and Dr. Lewis Lilley, whose special interest was pharmacology, was chosen as the Chairman of the Special Committee which compiled the first *National Formulary*.

Nominees on Ministry of Health Distribution Committees

The following nominees were accepted by the Ministry for appointment to the Central Distribution Committees for 1948–9 :

International Distribution Committee : Dr. E. A. Gregg (London), Dr. W. M. Knox (Glasgow), Dr. J. D. Wells (Billericay, Essex), and Dr. E. J. Rees (Pontypridd).

Distribution Committee for England and Wales : Dr. E. A. Gregg (London), Dr. W. Woolley (Bristol), Dr. E. J. Rees (Pontypridd), and the Secretary of the General Medical Services Committee of the B.M.A.; together with Dr. J. C. Pearce (Diss, Norfolk), Dr. J. D. Wells (Billericay, Essex), and Dr. C. F. R. Killick (Williton, Somerset), when questions concerning mileage are under consideration.

Medical Practices Committee

The medical profession's nominees on the Medical Practices Committee are : Dr. W. E. Dornan (Sheffield) (Chairman), Dr. P. V. Anderson (Shildon, Co. Durham), Dr. D. B. Evans (Wrexham), Dr. Annis Gillie (London), Dr. J. F. Murphy (London), Dr. J. C. Pearce (Diss, Norfolk), and Dr. J. A. Pridham (Weymouth).

Informal discussions have taken place during the session between members of the Committee and the medical members of the Medical Practices Committee. These discussions have been of value, and it is intended to maintain this useful liaison between the two Committees.

Central Health Services Council—Standing Medical Advisory Committee

The Chairman of the Committee was one of the Association's nominees for appointment to the Standing Medical Advisory Committee of the Central Health Services Council. Having regard to the status of the General Medical Services Committee as the recognized executive of general medical practitioners, the Committee feels that it is a matter of regret that the Minister has not seen his way to include the Chairman of this Committee in the personnel of the Central Health Services Council's Standing Medical Advisory Committee.

Joint Subcommittee of the Medical and Pharmaceutical Committees

Dr. W. Woolley (Bristol) was nominated for appointment to the Joint Subcommittee of the Medical and Pharmaceutical Committees of the Central Health Services Council.

Compensation Appeals Tribunal

An invitation was received from the Ministry of Health to nominate a practitioner to act as a medical assessor to the Appeals Tribunal, set up to deal with the situation where a practitioner is aggrieved by the assessment of the annual value of the goodwill of his practice. The Committee nominated Dr. A. N. Mathias (London, N.W.) for the appointment.

Joint Pricing Committee of England

Dr. Joel Green (London) was appointed to fill the vacancy on the Joint Pricing Committee of England caused by the death of E. Lewis Lilley.

CONSTITUTION OF GENERAL MEDICAL SERVICES COMMITTEE

The 1948 Annual Conference (Minute 19) requested the Committee "to review the mode of election and representation to the Committee and to report thereon." Also, it was suggested, in a motion referred to the Committee, that the Committee might be "reconstituted to form the executive body of all general medical practitioners, grouped within the framework of the B.M.A. into areas corresponding to the present B.M.A. Divisions." These suggestions have been carefully considered, but, having regard to the similarity between the local and central administrative structure of the old N.H.I. medical service and the corresponding service under the new Act, the conclusion reached is that very little change is necessary in the constitution of the new Committee.

The grouping of areas for the election of direct representatives of Local Medical Committees on the Committee has been carefully examined, and it is here that changes are recommended. Hitherto, numerical considerations have been regarded as more important than geographical considerations. In considering the future grouping of Local Medical Committees the Committee has borne in mind that Regional Hospital areas and the B.M.A. branch and division areas are not coterminous with Local Executive Council and Local Medical Committee areas, and the Committee has come to the conclusion that grouping for the election of direct representatives must be based on Local Medical Committee areas. Effective representation of these areas calls for a revision of the old grouping, and the Committee's proposals provide for an increase from 27 to 33 members directly elected.

It is felt that there is a strong case for retaining in the membership of the Committee a number of practitioners who

are elected by an "informed electorate" on their personal qualities, whatever the character or size of the area they represent. This would be achieved by the retention of the election of six members by the Annual Conference.

The question of co-option has been reviewed. It is proposed that the Committee should have power to co-opt up to four members, if necessary, to secure representation of a particular class of experience not otherwise represented on the Committee —e.g., a rural practitioner, a general practitioner not in the Service, a general practitioner employed also as a part-time specialist, etc.

Great importance is attached to the establishment of an effective liaison between the G.M.S. Committee and the Central Consultants and Specialists Committee. Two is considered to be the minimum for effective representation on each Committee.

Subject to the approval of the Conference, the constitution of the Committee for 1950–1 will be as follows:

5 *ex officio* (President of the B.M.A., Chairman of Representative Body, Chairman of Council, Treasurer, and Chairman of Conferences of Representatives of Local Medical Committees).
6 members elected by the Representative Body (4 for England and Wales, 1 for Scotland and 1 for Northern Ireland).
33 members elected on a territorial basis by Local Medical Committees in Great Britain and Northern Ireland.
6 members elected by the Annual Conference.
2 members nominated by the Central Consultants and Specialists Committee.
1 member nominated by the Medical Women's Federation.
1 member nominated by the Society of Medical Officers of Health.

54

with power to co-opt not more than four members, if necessary, to secure representation of medical practitioners of a particular class of experience not otherwise represented on the Committee.

Details of the grouping for the election of 33 direct representatives are given in Appendix "A."

RECOMMENDATION: That approval be given to the proposals in paragraphs 12–17 of the Report on the reconstitution of the General Medical Services Committee.

STANDING ORDERS OF CONFERENCES OF REPRESENTATIVES OF LOCAL MEDICAL COMMITTEES

The Standing Orders of the Conference have been reviewed and note has been taken of the suggestions made by the Conference for their amendment. The Committee also considered a proposal referred to it, that where two areas have been merged for Executive Council and Local Medical Committee purposes, the previous representation at the Annual Conference should be retained. The conclusion reached, however, is that representation must be based upon new Local Medical Committee areas, and that regard cannot now be had to a situation which no longer exists.

The proposed new Standing Orders are set out in Appendix "B," and will be incorporated in the Agenda of the forthcoming Annual Conference, for adoption or amendment by the Conference.

DATE OF FUTURE ANNUAL CONFERENCE

It has been customary to hold the Annual Conference of Representatives of Local Medical Committees in the autumn. This custom has certain disadvantages. It means that the Executive of the Conference—the General Medical Services Committee—is not complete and therefore unable properly to begin the work of the new session until the Conference has elected its six representatives on the Committee: nor is the Committee at its first meeting in the new session in possession of the views of the Conference on various outstanding matters. In other words, a late start is made on the Committee's work for the session.

It is felt that there would be advantages in holding the Annual Conference in the early summer, so that the new Committee may have its first meeting in, say, July. This would give the Committee a better opportunity of preparing for the main part of its work in the early autumn, instead of, as at present, some time in November or December. A summer Conference nearer the time of the Annual Representative Meeting of the B.M.A. would enable the views of both bodies on subjects of mutual interest to be co-ordinated. Subject to the approval of the Conference, the following Standing Order giving effect to this proposal will become effective in the summer of 1950:

(i) *Annual Conference of Representatives of Local Medical Committees.*—The General Medical Services Committee shall convene each year a Conference of Representatives of Local Medical Committees. The Conference shall ordinarily be held in June.

CONSULTATIONS ON REGULATIONS AND INSTRUCTIONS

The Ministry was asked for an assurance that the Committee would be consulted before any statutory orders were promulgated or instructions issued by the Department to Local Executive Councils or other bodies on matters of principle affecting doctors rendering services under Part IV of the Act. The Ministry has accepted "the general principle that the profession's representatives should be consulted on points of major principle involving regulations."

REMUNERATION

The 1948 Annual Conference instructed the Committee to take action "to secure an adequate overall increase in the capitation fee in order to relieve a serious hardship resulting from the new Service." The Committee began the task of carrying out this instruction by instituting an inquiry, to determine whether or to what extent the current incomes of general medical practitioners were in accordance with the main recommendations of the Spens Committee. Five areas were chosen —Lancashire, Norfolk, Bath, Halifax, and Nottinghamshire and Nottingham—and the figures obtained from these areas showed that, generally speaking, the "spread" of incomes in the 40–50 age group was in accordance with the Spens recommendation.

If these figures can be regarded as typical of the country as a whole, there remains the question of the "betterment" factor and the adequacy of the Central Pool, and on March 3 a Special Conference of Representatives of Local Medical Committees was called to consider the Committee's memorandum on the subject (M22, published in the *Supplement* of Feb. 19). In this memorandum the whole question of the adequacy of general-practitioner remuneration was discussed in detail, and the conclusion reached was that the Central Pool ought to be increased by approximately £16½ million. This conclusion was based largely upon an expert economist's calculation (*Supplement*, Jan. 22) that the change in the cost of living of professional classes between 1939 and the end of 1948 represented an increase of 85%. It also took account of the increased number of practitioners in the Service over and above the estimate upon which the Ministry based the present Central Pool.

The Committee's memorandum went on to recommend that any additional money made available in the Central Pool by the application of a proper betterment factor and an adjustment in relation to the increased number of practitioners in the Service should be devoted entirely to an augmentation of the capitation fee for the first thousand on all practitioners' lists. The effect of this would be to increase the remuneration of all practitioners while increasing the rate of remuneration of practitioners with smaller lists to a relatively higher extent.

The memorandum was approved by the Special Conference as the basis of the general-practitioner case, and the Committee was instructed "to press the Government as a matter of urgency to adjust general-practitioner remuneration on the basis of the memorandum, the adjustment being retrospective

to July 5, 1948." The memorandum and resolution of the Conference were sent to the Ministry on March 4. On April 14 it was learned that the Ministry had decided that insufficient information was available on which to assess how far the Spens recommendations were being implemented. The main factors were the number of doctors in the Service and the total amount each doctor was receiving from N.H.S. funds. Neither of these factors was known to the Ministry with any degree of precision, and a national inquiry had been instituted from the results of which it was anticipated definite conclusions could be reached. The Ministry hoped its inquiry would be available within a month, when its representatives would be in a better position to discuss the profession's claim for an increase in the Central Pool.

In the course of the discussion on April 14 the Ministry's representatives indicated that there could be no assurance that any improvement in remuneration which might emerge from this inquiry and subsequent negotiations would be applied retrospectively to July 5, 1948. Further, when asked what the position would be if, having raised the question of general-practitioner remuneration through Whitley machinery and in the event of disagreement, the G.M.S. Committee sought arbitration, the reply given was: "It must not be assumed without further discussion that participation in the Whitley machinery necessarily involves, in the event of disagreement, the right to resort compulsorily to arbitration on all subjects."

It was made quite clear to the Ministry's representatives that the statements on these two points were very unsatisfactory. It was regarded as unreasonable to inform the profession that it might not receive any increase in the "pool" retrospectively to July 5, 1948. The Ministry received ample notice of the profession's intention to raise the question of "betterment," and the profession was entitled to arrears of payment on this issue and on any increase in the number of general practitioners in the Service over and above the number (17,900) which was a factor in calculating the Central Pool before the appointed day.

On the question of arbitration, it was pointed out that the Ministry's statement was in conflict with repeated assurances given by Ministers, both in Parliament and personally, to representatives of the profession.

The Committee decided that no positive action could usefully be taken until the result of the inquiry undertaken by the Ministry was available. It was felt, however, to be necessary to place on record the profession's dissatisfaction with certain statements made to its representatives, and the following resolutions were sent to the Ministry:

"That the Committee records its dissatisfaction with the Ministry's inability to state, nine months after the appointed day, the number of principals taking part in the Service, and with the statement that, in so far as the Central Pool may prove to have been inadequate for the first nine months of the Service, any increase may not be adjusted retrospectively to the appointed day.

"That, in view of the statements made by responsible Ministers prior to the appointed day, the Committee is of opinion that the Ministry's view that disputes concerning remuneration referred through Whitley machinery do not carry the right to arbitration on either side is a gross breach of faith."

As stated in an earlier paragraph, the Ministry anticipated that the figures Executive Councils were being asked to furnish would be summarized and available by the middle of May, but it was learned subsequently that the result of the inquiry would not be available for many weeks. A request was therefore made for an interview with the Minister himself. On June 2 the Chairman and Secretary met the Minister, and the latter insisted that before any comparison could be made with the Spens Committee's recommendation it would be necessary to know what each doctor was earning, not only from the capitation fee but from all N.H.S. sources. Attempts to press the matter of the global sum were met with repeated reference to the necessity of computing each individual doctor's income before any decision could be made.

The Minister was informed that in certain circumstances the Committee might wish to ask for arbitration. While he did not rule out the possibility of arbitration being granted, he was unwilling to discuss this in relation to higher income groups. He repeated what had already been said by his officers, that participation in Whitley machinery did not carry the automatic right to seek arbitration on all matters.

The Minister was left in no doubt that the profession would be greatly disturbed at the turn which events had taken in the matter of arbitration. Subsequently, the Committee decided that, while no useful action could be taken on the question of the global sum until the result of the Ministry's inquiry was available, the profession should be fully informed of the seriousness of the situation and the vital need to preserve the right to a settlement by arbitration if agreement by negotiation could not be secured.

Following negotiations between the Joint Committee for Consultants and the Ministry on the terms and conditions of service for hospital medical and dental staffs, the following modified statement was issued by the Department:

The Ministry has agreed—

(*a*) That no changes will be made in the terms and conditions of service without discussion in the appropriate part of the Whitley machinery, when established, and this will be established as soon as possible.

(*b*) That remuneration is a subject which is suitable for arbitration.

(*c*) That save in exceptional circumstances, and after the conciliation machinery of Whitley has been exhausted, issues of remuneration remaining in dispute will go either to arbitration or for inquiry and report by a committee.

The G.M.S. Committee decided that this formula went some distance towards meeting the position of the general practitioners, and agreed to accept it without prejudice to any action it may be necessary to take when it is seen how the formula is applied.

Subsequently it was learnt that the detailed figures would be available at the end of July, and it is intended to reopen negotiations as soon as the Committee has had an opportunity of studying the figures. A special meeting of the Committee for this purpose is to be held on Aug. 31, if the figures are available in time.

MILEAGE

Very early in the Committee's deliberations on the subject of remuneration it became evident that many rural doctors throughout the country were in serious financial difficulties. Some would be able to carry on only if help was speedily forthcoming: others were considering practices in more populous areas. In some of the very remote parts of England and Wales the borders of medical practice are governed not by population but by geographical boundaries which are particularly effective in winter. Any depletion of doctors in these areas would be disastrous, but the possibility could not be excluded unless urgent remedies were applied.

Alleviation of the position of rural doctors seemed to be possible by only two methods—immediate and generous payments from the Special Inducements Fund, and/or a substantial increase in the Central Mileage Fund. There was a general reluctance on the part of doctors generally to apply for grants from the Special Inducements Fund because it seemed to them to be a form of "public assistance." Urgent representations were therefore made for a substantial increase in mileage payments, and the Ministry agreed to the Committee's recommendation that the Central Mileage Fund should be increased from £1.3 million to £2 million, the new money to be found from sources other than the Central Practitioners' Fund. The increase of £700,000 a year is made up of £200,000 from the Special Inducements Fund and a new Treasury grant of £500,000. Thus, the pre-war Mileage Fund of £600,000 has been more than trebled, and it is believed that the new money has gone a long way towards easing the financial position of rural practitioners.

The Committee's Rural Practitioners' Subcommittee has instituted an inquiry with the object of discovering, by comparison with the position which existed under the N.H.I. Act, the increase in the total number of patients in respect of whom mileage is claimed, the number of doctors claiming mileage, and the total number of mileage units claimed. Proposals for dealing with claims for special difficulties, such as footpaths under winter conditions, are also under consideration.

TEMPORARY RESIDENTS

Under the National Health Insurance Act the allocation to, and the charges against, individual Local Practitioners' Funds on account of temporary residents were based upon data furnished by Insurance Committees. The returns from Insurance Committees gave the number accepted by doctors, distinguishing between "ordinary" and "convalescent home" temporary residents. The payment from the Central Practitioners' Fund was 8s. for each ordinary temporary resident and 1s. for each convalescent home temporary resident, and each area was debited or credited on this basis. It involved a considerable amount of clerical work centrally for a relatively small sum before each area's "loading" could be determined.

Under the National Health Service the Ministry of Health obtained from every Executive Council a return showing the number of claims for temporary residents. Without making any "plus" and "minus" adjustment, each Executive Council was credited for the first two quarters (July to December, 1948) with 8s. for each temporary resident claimed.

The Committee felt that an increase in the unit value of a temporary resident was justified, but that any increase must be fair without being an unduly heavy charge on the Central Practitioners' Fund. After careful consideration it was decided

(*a*) that the amount deducted from the Central Practitioners' Fund for the treatment of temporary residents should be distributed to Executive Councils on a uniform basis in accordance with the number of claims from each area;

(*b*) that the value of the unit to be paid from the Central Practitioners' Fund should be 15s. for each ordinary temporary resident, and (provisionally) 2s. 6d. for each temporary resident in a convalescent home, to be reviewed in the light of experience and further information as to the number of claims received; and

(*c*) that claims for mileage for temporary residents should be charged to the Mileage Fund and not to the Central Practitioners' Fund for treatment purposes.

The Committee did not feel that it could make any recommendation in regard to the basis of distribution of the moneys received by Executive Councils for temporary residents, believing that this was entirely a matter for each area to determine by joint consultation between the Executive Council and the Local Medical Committee.

There appears to be some doubt as to the circumstances in which a claim for a temporary resident fee may be made. In the absence of a definition it is possible for a doctor to take a patient on his list as a temporary resident and claim a fee regardless of whether any treatment is given. The Committee considers that temporary resident credits should be given only in those cases in which medical treatment has been given, and the Ministry of Health has agreed to make this clear in the distribution scheme which is now in course of preparation. The Committee's definition would also apply to patients in convalescent homes.

BASIC SALARY

Circulars issued by the Ministry of Health to Executive Councils show that the Minister has allowed appeals against the disapproval of applications for basic salary in cases where the applicants have only recently established themselves in the area. The effect of granting basic salary to such practitioners is to subsidize them at the expense of their professional colleagues in the area, and it is contended that this is contrary to the Minister's original intention that doctors should not be encouraged to go to areas where they are not needed.

The Minister's attitude is understood to be that, having agreed with the profession's view that, up to the appointed day, every medical practitioner should have a right to choose the area in which he would enter the National Health Service, it would be impracticable to take any action which could be construed as being in conflict with that view. It is claimed that, subsequent to July 5, the Minister's responsibility was to consider, on its merits, every appeal against the disallowance of a claim for basic salary, without regard to the circumstances in which the appellant came to the district before July 5, 1948.

The Minister was asked to make provision in the proposed Amending Bill or Regulations for an appeal from the decision of a Local Executive Council on an application for basic salary to be made to the Medical Practices Committee and not to the Minister.

INFLATION OF DOCTORS' LISTS

In May last there were 20 Executive Council areas in each of which the numbers on doctors' lists were, in the aggregate, more than the estimated population of the area. This fact is quoted as evidence of the marked degree of inflation of doctors' lists, the main causes of which are:

1. Existence of a certain amount of inflation before the appointed day, partly from wartime difficulties and partly from the failure of some approved societies to notify "exits."

2. The decision not to remove from doctors' lists the names of persons whose insurance was due to terminate on June 30, 1948. The numbers were fairly substantial, being largely people who had taken up work during the war or had continued to work when they might otherwise have retired, and who ceased to be employed between June 30, 1946, and Dec. 31, 1946.

3. The action of many insured persons in completing form E.C.1. The identification of duplicates involved a tremendous amount of work and was made more difficult by conflicting or insufficient information on form E.C.1, and the completion of more than one E.C.1 by a number of insured persons and by others who did not immediately receive a medical card.

4. The appearance of some persons' names on more than one doctor's list not necessarily within the same Executive Council area. Some of these were insured persons before July 5, 1948.

5. Removal of a person from one Executive Council area to another where registration is effected with a doctor in the new area without disclosure of the fact that the patient is on the list of a doctor in the other area.

6. Men going into the Forces receive a new identity number when they return to civil life. Representations have been made with a view to the retention of the old number.

The position has been discussed with the Ministry with the object of checking the causes of inflation or bringing them within reasonable limits. The elimination of duplicate names—perhaps the main cause—will be a lengthy process, owing to the need for inquiry in many cases where duplication is suspected but cannot be established from Executive Council records. Constant scrutiny of lists will help to reduce duplication, but many cases will be resolved only by personal inquiry of the persons concerned. In this connexion it is felt that the provision of reply-paid envelopes or labels might secure a higher percentage of replies. Doctors and patients can help by notifying Executive Councils of changes of address and by completing form E.C.1 only where one has not previously been completed and where no medical card is held.

The Ministry has undertaken to do everything possible to speed up the process of clearing doctors' lists. If no substantial reduction of inflation is effected by 1951, when the new census is taken, consideration will be given to the establishment of a Central Index Register, which the Ministry regards as quite impracticable at the present time.

New Form E.C.1

The readiness with which the present form E.C.1 is available and can be used, even when a medical card is available and ought to have been used, is responsible for a certain amount of inflation of doctors' lists. It often happens that a person who cannot find his medical card, instead of getting a new one, completes another form E.C.1, and the information given on that form may not reveal the fact that the person is already on another doctor's list. It has been decided, therefore, that it would be useful to have a simpler form which would be available only from doctors or the offices of Executive Councils. The new form will contain a declaration to be made by the person completing it, stating that the applicant "is not already on the list of a doctor in this or any other area."

REMOVAL OF NAMES FROM DOCTORS' LISTS

The Ministry has accepted the Committee's suggestion that when a notice or medical card is returned to the Executive Council through the Dead Letter Office the person's name should not be removed automatically from the doctor's list before six months have elapsed, during which time the doctor will be given an opportunity of supplying information as to the patient's whereabouts.

ANAESTHETICS

'TRILENE'—in addition to its use in analgesia—is employed with success for the production of a light plane of anaesthesia. Contra-indications are few, and recovery is rapid with no unpleasant after-effects.

Containers of 250 and 500 c.c. Crushable ampoules of 1 c.c. in boxes of 5; ampoules of 6 c.c., boxes of 1, 5 and 25.

'KEMITHAL' SODIUM is a highly efficient ultra-short-acting barbiturate used for induction and surgical anaesthesia of short or prolonged duration. Notable features of its use are minimal respiratory depression and a consistently good post-operative recovery, free from vomiting, restlessness and protracted depression.

Ampoules of 1 or 2 grammes, with or without distilled water. Containers of 5 and 25.

Other anaesthetics and analgesics include: 'Avlon' brand Chloroform, Procaine, and Pethidine (with and without Hyoscine).

Vasodilatation

There is considerable evidence of the outstanding value of Cardophylin in producing vasodilatation. The coronary vasodilatation is manifested in an increased coronary blood flow and a beneficial effect on the myocardium; the renal vasodilatation is indicated by the powerful diuresis. It also causes bronchodilatation.

Avoid
flogging a tired horse

CHANGES in normal routine and restricted or special diets may induce constipation. Purgatives, however, overstimulate the bowel temporarily and this is followed by inactivity. The tired horse—so to speak—is flogged again and a vicious circle results.

Regular effort and adequate bulk are needed to restore normal routine. 'PETROLAGAR' provides the 'soft bulk' essential to regular peristalsis. Gently but surely it helps the return to 'habit time.'

'PETROLAGAR,' a 25% emulsion of white petroleum oil with flavouring, is issued in two varieties: Plain and with Phenolphthalein.

MISSING INFORMATION ON FORMS E.C.1

Complaints were received that some Executive Councils were asking doctors to obtain information which patients had failed to give on form E.C.1. The point was taken up with the Ministry, who agreed that it was the duty of the Executive Council to apply direct to the patient for the missing information.

FILLING OF VACANCIES CAUSED BY DEATH OR RETIREMENT

Two informal conferences were held between representatives of the Committee and the medical members of the Medical Practices Committee, at which representatives of the Scottish Medical Practices Committee were present. At these conferences questions which were giving rise to difficulties in connexion with vacancies caused by the death or retirement of doctors were discussed. As a result, the Ministry was asked to provide in the Amending Bill for

(*a*) the law to be brought into conformity with the Minister's promise that, in all areas except those where the Medical Practices Committee has decided that no more doctors are needed in the Service, the consent of that Committee to applications for inclusion in the medical list will be automatic;

(*b*) the filling of a declared vacancy to be followed automatically by the "block" transfer of the patients by the Medical Practices Committee, the transfer being made to the practitioner finally selected;

(*c*) power being given to Local Executive Councils to remove from their lists practitioners (other than those compulsorily recruited to H.M. Forces) no longer working in the area and no longer providing the appropriate premises;

(This point was subsequently included in the Amending Bill.)

(*d*) the right of appeal by an Executive Council to the Minister when the Medical Practices Committee has reversed the decision of the Council.

A new form (to be known as E.C. 16A) is in course of preparation for use by applicants for an advertised vacancy. Amending regulations are also being drafted (*a*) to provide that *all* applications received for an advertised vacancy (including those made by applicants already on the list) shall be referred to the Medical Practices Committee, who would make the selection, and (*b*) to extend the right of appeal to *all* unsuccessful applicants. At present those already on the list have no such right of appeal.

It is understood that the Treasury will sanction only third-class travelling expenses for doctors who are candidates appearing before an Executive Council in connexion with a vacancy in the area. The Ministry has undertaken to make further representations to the Treasury on the subject.

VOLUME OF WORK DONE BY GENERAL PRACTITIONERS

The volume of work general practitioners would be called upon to do could not be assessed when the Service commenced, and, in the absence of reliable data, could not be taken into consideration during the discussions on remuneration. As a first step towards obtaining reliable data, the Committee has decided to conduct a special investigation covering a period of one year. A similar investigation was undertaken in 1938–9, but, although the results confirmed figures previously obtained by another method, the abandonment of the Insurance Acts Committee's application for increased remuneration (owing to the outbreak of war) meant that they could not be used. This new inquiry, which will begin in October, will be under the supervision of an expert statistician.

VACCINATION AND IMMUNIZATION

Discussions with representatives of Local Authorities on the fees to be paid for vaccination and immunization were adjourned until the Committee had settled with the Ministry of Health the question whether these services fall within the scope of a general practitioner's agreement under the National Health Service Act. The Ministry has now agreed that the submission of a report is not the only factor to be taken into account in fixing appropriate remuneration for these services, and has been asked to reopen discussions with the Local Authorities Associations as soon as possible. To hasten these negotiations the Committee has informed the Ministry that unless discussions on the fees to be paid for vaccination and immunization are reopened forthwith the Committee will take no steps to discourage Local Medical Committees from advising their constituents not to send records of persons vaccinated and immunized to local authorities. Any settlement will cover all cases dealt with since July 5, 1948.

CERTIFICATION

Inter-Departmental Committee

Representatives of the Committee (Drs. S. Wand, E. A. Gregg, and F. Gray) have given oral evidence before the Inter-Departmental Committee on Certification.

Hospital Out-patients

The Ministry of Health suggested that forms Med. 7 and 8 for use in connexion with long-stay patients in hospitals might be adapted for issue to out-patients. The Committee took no exception to the proposal, but expressed the hope that appropriate steps would be taken to ensure the maintenance of a high standard of certification.

Certificates for Juveniles and Non-employed Persons

Inquiry was made as to whether it was part of the general practitioner's terms of service to give certificates free of charge to juvenile and non-employed persons who did not require such certificates for National Insurance purposes. The Ministry pointed out that, so far as juveniles were concerned, a certificate was required in order to get a "credit" and to obviate the requirement of a stamp. The suggestion that this is a matter which should be taken up with the Inter-Departmental Committee on Certification has been adopted.

Certification for Surgical Corsets

Discussions have taken place with representatives of the Ministry of Health and the Board of Trade with a view to relieving practitioners of the burden of certification for surgical corsets. The Ministry and the Board have agreed to waive the requirement, and an appropriate circular has been issued to the trade. The Customs and Excise, however, still require a medical certificate to substantiate a patient's claim for exemption from purchase tax, and until this latter point has been cleared up a medical certificate is still necessary.

Certification of Contacts

The Committee has taken up with the Ministry of National Insurance an instruction to the effect that, in certain circumstances, only a certificate issued by a Medical Officer of Health to a suspected carrier or contact in cases of infectious diseases would be recognized for National Insurance purposes. The Committee has been assured by the Ministry that this instruction was issued with purely epidemiological considerations in mind, and that there is no intention of encroaching on the rightful province of the family doctor.

Morbidity Statistics

General approval has been given to a proposal by the Ministry of National Insurance that the final medical certificate should be used in the compilation of morbidity statistics.

DISPENSING AND PRESCRIBING

Provision of Medicines and Appliances for Private Patients

There is general agreement among general practitioners that patients who wish to make private arrangements for medical attention and treatment should not be debarred from obtaining necessary medicines and appliances through the National Health Service. This question has been pressed on the Ministry of Health, whose view is that prescribing and dispensing are essential parts of treatment and cannot be dealt with as though

they are something separate. The Ministry was asked to consider the possibility of making available, through the Hospital Service, to patients treated privately, particularly expensive and life-saving medicines (insulin and liver preparations, etc.) where the cost would represent hardship to the individual, but the Ministry does not think that any workable arrangement on these lines is possible. Efforts have been made to secure an amendment of the Act to give effect to the profession's wishes in this matter.

Dispensing Capitation Fee

The Ministry's offer of a capitation fee of 6s. 6d., in England and Wales, to cover the provision of medicines and appliances (except those contained in a special list) for patients who would otherwise have difficulty in obtaining them from a chemist has been accepted without prejudice to revision as a result of negotiations at a later date. Before the fee is reviewed, there will be an investigation into dispensing costs. Doctors who are required to dispense for their patients may, of course, choose the alternative method of being paid, namely, on a "cost per prescription" basis.

Medicines and Appliances for Doctors' Surgeries

The Ministry has been asked to accept the Committee's suggestion that doctors should be allowed to order, on official prescription forms, stocks of medicines and dressings for emergency use in surgeries. Scottish general practitioners already enjoy this privilege.

List of Appliances

The Ministry has been asked to include the following in the list of appliances and chemical reagents which general practitioners may prescribe for their patients:

B.L.B. mask for the administration of oxygen (where not already provided by the local health authority).
"Cellanband" bandage.
"Clinitest" apparatus (under "chemical reagents").
Adhesive sponge rubber.

It has been suggested also that the words "as described in the Drug Tariff" should be deleted from the reference to dressings, thus giving the doctor greater freedom in prescribing them.

The Ministry has indicated that it is not possible to allow general practitioners complete freedom to prescribe surgical appliances. The Department is prepared, however, to receive suggestions for a list of surgical appliances which it is considered general practitioners should be able to prescribe without referring the patient to the Hospital Service, and such a list is now in course of preparation.

Specially Expensive Drugs and Appliances

The Ministry has agreed to add ethisterone to the list of drugs and appliances and reagents for the supply of which dispensing doctors paid by capitation fee receive payment over and above such fee.

The Committee also asked for the inclusion of (*a*) hypodermic syringes and needles (for all purposes, and not only for the self-administration of insulin or adrenaline, as at present), (*b*) "clinitest" apparatus, and (*c*) all sulphonamide drugs. So far as (*a*) and (*b*) are concerned, their inclusion would necessitate an amendment of the Regulations, which is under consideration as they are not at present permitted to be supplied at all under the general medical services. On the question of sulphonamide drugs, the Ministry is not agreeable to the inclusion of all of them, but is willing to consider any suggestions the Committee may wish to make. The Ministry has agreed to continue, on a temporary basis, the arrangement in force under the N.H.I. Act which permitted dispensing doctors to submit claims for special payment in cases where the cost of dispensing was abnormally high. The minimum amount it will be possible to claim under this heading is twenty shillings in respect of one quarter. The arrangement will be reviewed concurrently with the review of the dispensing capitation fee.

Pessaries and Dutch Caps

The Ministry suggested, and the Committee agreed, that doctors should be permitted to supply pessaries under the Service, and paragraph 7 (9) (ii) of the terms of service has been amended accordingly.

The Committee's suggestion that Dutch caps should also be included was not accepted by the Ministry, but it is understood that this is part of the wider question of contraceptive advice by general practitioners now under consideration by the Standing Medical Advisory Committee of the Central Health Services Committee.

Prescription Books

The present unsatisfactory "lay-out" of the prescription form and the construction of pads of these forms have been among the subjects discussed with the Ministry.

Prescribing for Residential Schools and Institutions

It was suggested to the Ministry that, with a view to economy of public funds, when prescribing for residents of schools and institutions a practitioner should be able to prescribe for the school or institution as a whole by means of a bulk prescription.

The Department has accepted the suggestion in principle so far as medicines are concerned, but will not agree to the inclusion of dressings owing to the possibility of abuse.

Inter-Prescribing by Industrial Medical Officers

In certain areas where the majority of the practitioners are part-time medical officers to local factories, it has been found that during sessions at the factories the Medical Officer has been asked to see another doctor's patient, who obviously should go home and would benefit from a prescription being given that day. It has been suggested that the Industrial Medical Officer should prescribe for such a patient and write a brief note to the patient's doctor, to be handed to him when he visits the next day.

The Committee is in agreement with the Occupational Health Committee of the Association that it is undesirable that Industrial Medical Officers should prescribe in these circumstances.

MATERNITY MEDICAL SERVICES

Administration of Anaesthetics

It was suggested to the Ministry of Health that the fee for the services of a second doctor administering an anaesthetic in a confinement should be paid direct to the doctor. The suggestion was not pressed, in view of administrative difficulties, particularly in the matter of superannuation.

Certificates of Incapacity due to Pregnancy

The Ministry of National Insurance has agreed to the Committee's proposal that at or about the 34th week of pregnancy the doctor should be required to give only one certificate to cover the interval of the actual confinement. A new type of certificate has been prepared which will enable the doctor to issue only one certificate eleven weeks before the expected date of confinement. In the event of the anticipated date being incorrect, no further certificate will be required. An ordinary weekly certificate will be required for sickness benefit prior to the beginning of the eleven-week period. This new certificate should ease the present burden of certification at present falling on doctors.

Payment of Fees for Maternity Services

The Ministry agreed with the view put forward by the Annual Conference (Minute 70) that the payment of fees for maternity medical services should not be dependent upon the carrying out of an examination on a particular date, and has so informed Executive Councils. It has also been agreed that Executive Councils should give doctors the names of patients in respect of whom payments are being made, and the amount payable in each case.

Miscarriages

The Committee contested the Ministry's view that treatment for miscarriages should be regarded as part of the ordinary obligation of a general practitioner under his terms of service, and the Ministry has since agreed that a doctor may claim a Part I fee for attending a miscarriage after the eighth week of the commencement of pregnancy.

Similarly, the Ministry has agreed that emergency confinements should qualify for Part II payment, provided the patient is not booked with any other doctor and the doctor is not called in by a Local Authority midwife.

Mileage in Maternity Cases

The Ministry has been asked to agree that a practitioner practising in an area where a mileage scheme normally operates, whether he is on the obstetric list or not, should be entitled to a single payment for each maternity case booked, at the rate of 3s. a mile (outwards) over two miles from the practitioner's residence to the patient's address. The payment will be a first charge on the Central Mileage Fund.

Forms of Application for Maternity Benefit

Arrangements have been made for a supply of forms of application for maternity benefit to be made available to individual practitioners where desired.

Sterile Drums for Domiciliary Midwifery

The present position in regard to the supply of maternity outfits and dressings is as follows:

(*a*) Where a Local Authority midwife is attending the case, both maternity outfit and dressings will be supplied free of charge. Normally the expectant mother would be expected to collect the outfit from the nearest clinic, but if this is not possible (e.g., in remote rural areas) she should write to the Local Authority, who will probably send a health visitor to her home.

(*b*) Where the expectant mother has booked no midwife, or a private midwife, the Authority may still supply a free maternity outfit—obtained as in (*a*)—if requested, though not the extra dressings for the lying-in period.

(*c*) Where the expectant mother is receiving maternity medical services under Part IV and has booked a private midwife, the position will be as in (*b*) above.

(*d*) Where the expectant mother has booked her confinement at a private maternity home the Local Health Authority will not be responsible for providing outfit or dressings.

The Ministry has been asked to extend these arrangements to all confinements whatever arrangements may have been made.

Definition of a G.P. Obstetrician's Responsibility towards Patients not on his N.H.S. List

The Committee felt it was desirable to attempt to define the general-practitioner obstetrician's responsibility in regard to conditions arising out of and during pregnancy, and has approved the following statement for guidance in dealing with inquiries on this subject:

In all cases where a general-practitioner obstetrician's responsibility is in doubt, it is desirable that there shall be consultation between him and the patient's ordinary medical attendant. Any question where there is an unresolved difference of opinion should be referred to the Chairman or Secretary (being a medical practitioner) of the Local Medical Committee, whose decision would be binding.

Although it is impossible to compile an exhaustive list of conditions occurring during pregnancy for the treatment of which the general-practitioner obstetrician could reasonably be expected to accept responsibility, the following are put forward as the nucleus of such a list:

Toxaemia of pregnancy.
Antepartum haemorrhage.
Any pelvic or vulval abnormality arising out of or in the course of pregnancy.
Genito-urinary infections.
Severe hyperemesis gravidarum.
Responsibility in puerperium only for 14 days, except for post-natal examination at or about the sixth week.

Assistants Employed for Maternity Medical Services

Following representations by the Committee, the Ministry has amended the Regulations to enable an Executive Council to waive the requirement that a deputy or assistant employed for maternity medical services must have obstetric experience.

Review of General Practitioners on Obstetric List

A letter from an Executive Council to all doctors on the Obstetric List for the area indicated that the list was to be revised, and inquired whether the doctors concerned claimed to have special experience in obstetrics and wished to continue to have their names on the list. The question is being raised with the Ministry from the point of view that doctors who have gained admission to the list should be given reasonable security of tenure.

MEDICAL SERVICES COMMITTEE PROCEDURE

It was represented to the Committee that provision should be made for a medical practitioner to be allowed to have legal assistance in the presentation of his case before a Medical Services Committee. The Committee is not in agreement with this view and has decided that, for the present, no action should be taken to secure an amendment of the regulations. At the same time, at the end of a reasonable period the Committee intends to review the various regulations affecting the terms of service of general medical practitioners, and Local Medical Committees will be asked to report on their experience of the working of the Regulations, including the procedure at meetings of Medical Services Committees. A special subcommittee has now been appointed to make a survey of the constitution, procedure, and working of Medical Services Committees, and will have before it a resolution passed by the Representative Body of the Association to the effect that the regulations relating to the procedure of Medical Services Committees should be amended to bring them into line with those applicable to Northern Ireland whereby a defendant doctor appearing before a Medical Services Committee may have, if he so desires, the services of a paid advocate or solicitor.

The position of the Deputy Chairman of a Medical Services Committee when the Chairman is present has been raised with the Ministry of Health. The Ministry's view is that the Deputy Chairman may be present and may take part in the proceedings as though he were an ordinary member, but he may not vote. The Committee feels that, whilst the Deputy Chairman should be entitled to be present, he should be debarred from taking any part in the proceedings, nor should he vote, and the Ministry has been asked to amend the appropriate regulation accordingly.

The Regulations governing the consideration of complaints against a medical practitioner do not provide, as in the old N.H.I. Benefit Regulations, for similar action against a patient. Although such complaints are rare, the Committee felt that provision should be made for them under the new Service, and representations have been made to the Ministry of Health on the subject.

RANGE OF SERVICE

The Committee has agreed with the Ministry's ruling that the taking of a sample of blood for examination for the Rhesus factor falls within a general practitioner's obligations under the Act.

SPECIALIZATION IN GENERAL PRACTICE

Paragraph 10 (1) of the terms of service for general practitioners precludes a practitioner from demanding or accepting any fee or other remuneration in respect of any medical treatment, "whether under these terms of service or not, rendered to his patients or the patients of his partner or assistant." A proviso sets out certain exceptions, but, generally speaking, a doctor who has the requisite qualifications and experience to enable him to render services which are normally outside the scope of general-practitioner treatment may not now charge for these additional services.

The view of the Committee is that it is essential, in the interests of medicine, that some degree of specialization in general practice should be encouraged, and this view has been constantly emphasized in discussions with officers of the Ministry of Health. The Ministry's view is that facilities for specialist services are provided under the Act without charge to the patient, and that a general practitioner cannot receive payment for specialist services unless he is also employed as a specialist in the Hospital Service. In pursuance of some relaxation of this rigid rule, the Committee is seeking a definition of "medical treatment" in the Regulations. In the meantime a memorandum entitled "The Case for Physiotherapy" has been sent to the Department in support of the Committee's case, and the Ministry has undertaken to explore the possibility, so far as rural practice is concerned, of allowing a general practitioner with the requisite experience to participate in the physiotherapy service as part of the Hospital Service but not necessarily as a specialist.

GENERAL PRACTITIONERS AND HOSPITAL WORK

The Council of the Association has appointed a Committee to consider and report upon the association of general practitioners with hospital work. The Private Practice, General Medical Services, Public Health, and Central Consultants and Specialists Committees each have three representatives on the Committee. The General Medical Services Committee's representatives are Drs. S. Wand (Birmingham), D. F. Hutchinson (London), and C. F. R. Killick (Williton, Somerset).

Treatment in Cottage Hospitals

The Annual Conference (Minute 98) expressed dismay that doctors not participating in the National Health Service were not being permitted, as in the past, to attend their own patients in cottage hospitals. An assurance has been received from the Ministry that it is their policy to encourage general practitioners to join the open staffs of cottage hospitals. The Ministry is willing to investigate any case brought to its notice.

GENERAL PRACTITIONERS AND SPECIAL DEPARTMENTS OF HOSPITALS

The Ministry of Health was asked to assist in securing that there should be extended to all general practitioners the privileges, now enjoyed by some, of being able to obtain *x*-ray and pathological examinations by direct application to the hospital department concerned. The problem is said to be the practical one of increasing facilities so that the hospital departments can meet the needs of general practitioners as well as their primary duties to the Hospital Service. Whilst recognizing that the difficulty is a practical one, the Committee considers that increased facilities are more likely to be available in the field of pathology, particularly where they are not provided as part of the Hospital Service.

GENERAL-PRACTITIONER SPECIALISTS

A subcommittee composed jointly of members of the General Medical Services and Central Consultants and Specialists Committees has been appointed to consider matters of particular interest to general-practitioner specialists. The G.M.S. Committee's representatives are Drs. A. T. Rogers (Bromley), W. D. Steel (Worcester), and H. S. Howie Wood (Isle of Wight). This joint subcommittee, which has met on three occasions, has been predominantly concerned up to the present time with the problems arising out of the assessment of status of practitioners engaged in the hospital and specialist services.

Before the deliberations of Review Committees became known, there was a growing anxiety among general-practitioner specialists that as a body they would be downgraded to the status of Senior Hospital Medical Officer, despite the instructions of the Ministry of Health that the assessment of status should be made on the merits of the individual practitioner, account being taken not only of higher qualifications but of actual experience. The subcommittee therefore recommended to the Joint Committee that any general practitioner holding a specialist appointment on the staff of a closed hospital, or where he had full clinical responsibility, should be recognized as of specialist status, enjoying the same security of tenure and remuneration as other specialists, provided he satisfied the Review Committee, bearing in mind the general instructions of the Ministry regarding the assessment of status. The subcommittee also recommended (*a*) that the Review Committees should be encouraged to seek evidence of the practice of a specialty; (*b*) that they should have regard to the views of Local Medical Committees; and (*c*) that a general-practitioner specialist should be co-opted to the Review Committee when the status of other general-practitioner specialists was being considered. The General Medical Services Committee has gone a step further by sending the following resolution to the Ministry of Health:

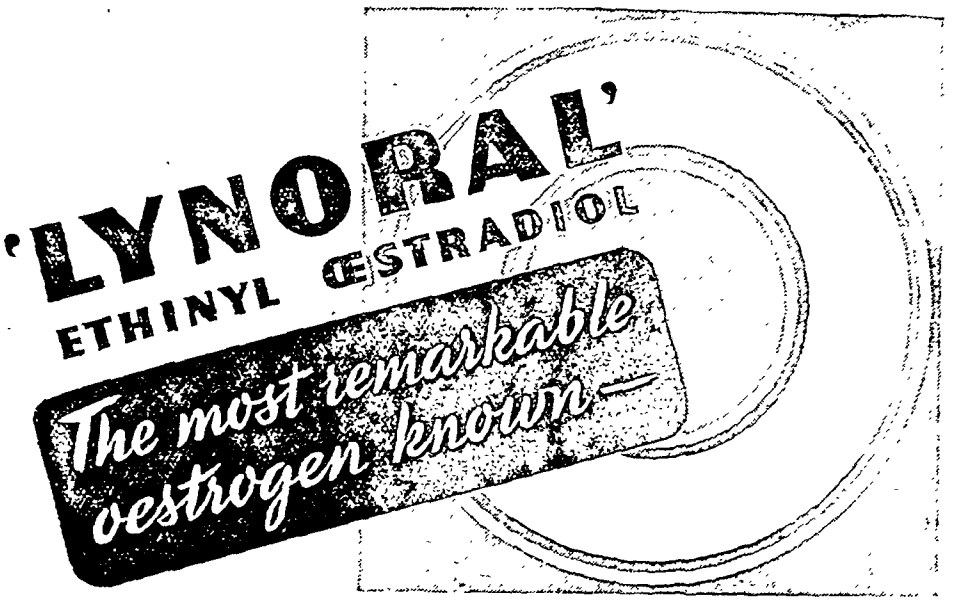
"That this Committee, being informed of the widespread dissatisfaction throughout the country on the part of general-practitioner specialists who consider that they have been improperly graded, wishes to press for the establishment of appeal machinery independent of the body responsible for the original assessment."

Now that the decisions of Review Committees have largely been announced, it has been found that not only general-practitioner specialists but a considerable number of exclusive specialists have been graded as Senior Hospital Medical Officers, and the problem is therefore a general one which is exercising the attention of the Central Consultants and Specialists and Joint Committees.

In the meantime the subcommittee has expressed the view that in order to afford the necessary opportunity for a general practitioner, graded as a consultant, to maintain his skill and efficiency he should be offered and required to undertake not less than three or more than five sessions per week; and that when he wishes to do more than five sessions he should, except where his other commitments are unusually light, consider transferring to the exclusive practice of his specialty. In general, the subcommittee considers the same consideration should apply to general-practitioner specialists graded as Senior Hospital Medical Officers, but in this case there might be circumstances in which less than three weekly sessions should be permissible.

The subcommittee has asked the Joint Committee to give early consideration to the present and future position regarding the employment of general-practitioner specialists and to allow its chairman to attend to submit the views of the subcommittee.

LIAISON BETWEEN GENERAL PRACTITIONERS AND CONSULTANTS



The Committee is exploring the practicability of promoting liaison between general practitioners and consultants at Regional, Hospital Management, and Group Committee levels.

REMUNERATION OF GENERAL PRACTITIONERS ON STAFFS OF COTTAGE HOSPITALS

According to the draft permanent terms of service for hospital and specialist work, general practitioners on the staff of a cottage hospital are to be remunerated from a staff fund, created by the Hospital Management Committee making a payment of £25 per annum for each bed (other than private pay-beds) occupied on the average in the hospital, the fund to be shared among the general-practitioner staff as they may themselves determine. There have been some complaints that this payment is inadequate, especially as it does not take account of the work done for the doctors' own patients when they are in hospital, work which involves the administration of anaesthetics, assistance at operations, post-operative treatment, etc. This aspect of the problem will be considered by the Committee in conjunction with the settlement of the Central Pool for general medical services.

PART-TIME MEDICAL OFFICERS OF CONVALESCENT HOMES

Part-time medical officers of convalescent homes or other types of hospital where no other rate is applicable are, according to the draft permanent terms and conditions for hospital and specialist work, to be remunerated at the rate of £175

FOR ORAL ADMINISTRATION

DERIVED FROM THE NATURAL OESTROGEN

EXTREME POTENCY MEANS

MINUTE DOSAGE WITHOUT SIDE EFFECTS

AT LOW TREATMENT COST

For all conditions where oral Œstrogen therapy is indicated

Tablets of 0.01 mg. and 0.05 mg. (scored)

Tubes of 25. Bottles of 100 and 500.

Samples and full literature on request

ORGANON LABORATORIES LTD.

BRETTENHAM HOUSE, LONDON, W.C.2

TELEPHONES: TEMPLE BAR 6785/6/7 0251/2

TELEGRAMS: MENFORMON, RAND, LONDON

*in equivalent doses, no barbiturate for oral use combines more rapid, profound and shorter effect than . . .

Nembutal

REGISTERED TRADE MARK

(BRAND OF PENTOBARBITONE SODIUM B.P.)

FOR SEDATIVE EFFECT—Nembutal ½-gr. or ¾-gr. capsules.
* Nembutal is a *powerful* barbiturate—so powerful that doses of less than 1½-gr. suffice for many patients and in many conditions in which brief sedative and only a mild hypnotic action is desired.
* In simple insomnia, for instance, a dose no larger than one ¾-gr. capsule usually subdues emotional disturbances or reactions to outside stimuli sufficiently to induce sleep.
* Smaller dosage reduces the amount of the drug that must be eliminated, the duration of effect, and any slight possibility of "hangover."

FOR TRUE HYPNOSIS—Nembutal 1½-gr. capsules.
* Only one 1½-gr. capsule is needed in most circumstances to produce 6 to 8 hours of sleep under the influence of the drug.
* For preoperative sedation and as a basal anaesthetic, prescribe one or two 1½-gr. capsules the evening before, and one or two capsules of the same size one or two hours before operation.
* For obstetrical analgesia and amnesia, administer two or three 1½-gr. capsules with or without scopolamine, when cervix is definitely dilated, and pains recur regularly at not more than five-minute intervals.

A form to fit any short-acting sedative and hypnotic need

NEMBUTAL ½ & ¾-gr. CAPSULES—for the majority of cases in which sedative effect only is required.

NEMBUTAL 1½-gr. CAPSULES—for surgical, obstetrical and all requirements for true hypnotic action.

NEMBUTAL ELIXIR—contains 2 gr. per fluid ounce, ¼ gr. per teaspoonful, in a palatable form.

NEMBUTAL SUPPOSITORIES—in 2-gr. size.

NEMBUTAL and ASPIRIN—NEMBUTAL, ½-gr., and ASPIRIN 5-gr. Sedative and analgesic.

EPHEDRINE and NEMBUTAL—EPHEDRINE ⅜-gr. and NEMBUTAL ⅜-gr.

ABBOTT LABORATORIES LTD., WADSWORTH ROAD, PERIVALE, MIDDLESEX

per annum per weekly "half-day" up to a maximum of nine "half-days" per week. This approximates closely to the rate to be paid to specialists, and is considered to be reasonable.

DOMICILIARY CONSULTATIONS

The Committee supports the views of the Central Consultants and Specialists Committee, as expressed in the following resolutions:

Resolved: That in the opinion of the Committee, whilst it is most desirable that a general practitioner who requests a domiciliary visit by a consultant should be present at the consultation, he should not be required by regulation so to attend.

Resolved: That the G.M.S. Committee be informed that in the view of the Committee general practitioners should not be required to furnish written certificates in connexion with domiciliary visits carried out by consultants at their request.

Resolved: That in all cases where requests for domiciliary visits are required to be made through the hospital the diagnosis should not be disclosed, and the reason for the request confined to a statement that the patient is "unfit to attend hospital."

The 1948 Annual Conference referred to the Committee a motion objecting to the method of obtaining the service of consultants for domiciliary consultations, which interfered with the normal personal relationship between general practitioner and consultant. The Central Consultants and Specialists Committee was asked for its observations on the point and replied as follows:

"Isolated complaints have been received from local units of the B.M.A. with regard to the domiciliary visiting arrangements and in particular to the requirement that requests for domiciliary visits should be made through the hospital and not by direct approach to the consultant.

"The Committee does not consider it unreasonable that requests for domiciliary consultations under N.H.S. arrangements should be made through an official channel, nor does it feel that the arrangements interfere unduly with the relationship between general practitioner and consultant in view of the fact that once the official request has been made there is nothing to prevent direct contact between the two practitioners.

"The Committee also suggests that the present arrangement preserves the distinction between public and private practice."

It has been suggested to the Central Consultants and Specialists Committee that the general practitioner should have the alternative of being allowed to make arrangements for a domiciliary consultation through the hospital or by direct approach to the consultant.

ASCHHEIM-ZONDEK TESTS

The Ministry advised Local Executive Councils that Aschheim-Zondek tests could be carried out as part of the National Health Service only by reference to a specialist at a hospital. The Committee pointed out that it had been a common practice for doctors to obtain these tests by direct application to a laboratory, and that it was quite unnecessary for a patient to be referred to a specialist before the test could be undertaken.

The Ministry has since agreed that, wherever arrangements can be made without the intervention of a specialist, it will be possible for a general practitioner to obtain an Aschheim-Zondek test direct. The procedure will be evolved with the least possible delay.

SUPERANNUATION

At the Committee's request, the Ministry has amended regulation 38 of the Superannuation Regulations so as to make it clear that there must be agreement between partners before an Executive Council can be authorized to assess superannuation contributions on the basis of shares in the partnership.

The Association's Superannuation Committee has been asked to secure that all remuneration from N.H.S. and Local Authority sources shall rank for superannuation. Representations to the Ministry have repeatedly been made on this point.

The exclusion of an assistant's remuneration in assessing a principal's remuneration for superannuation purposes has been taken up with the Ministry. It is considered to be inequitable that the salary paid to an assistant should be deducted from a practitioner's gross remuneration, in addition to the normal deduction (35%) for practice expenses, when assessing the net income to rank for superannuation. The Ministry has undertaken to explore with the Treasury an alternative proposal that the principal should be relieved of his present obligation to pay the employer's contribution to his assistant's superannuation.

ASSISTANTS

The position of assistants to general practitioners in the National Health Service needs clarification, and with this object in view the following proposals were submitted to the Ministry:

(*a*) That the names of assistants should be incorporated in a separate list;

(*b*) that there should be a right of appeal to the Medical Practices Committee against the refusal of an Executive Council to consent to the employment of any assistant;

(*c*) that the Local Executive Council should have a right to participate in the proceedings of such an appeal;

(*d*) that consent to the employment of a second assistant should not be subject to the approval of the Medical Practices Committee;

(*e*) that an assistant should not be allowed to have his own list of patients.

These proposals have been discussed at a conference of representatives of the G.M.S. Committee, the Ministry, the Executive Councils' Association, and the Medical Practices Committee. There was no difference of opinion on points (*b*), (*c*), and (*e*).

On point (*a*) there is general agreement that assistants' names should not be included in the medical list or in a separate list. In future this will probably be a condition of the right of a doctor to employ an assistant, but no change will be made in the present position so far as assistants already on the list are concerned.

On point (*d*), the employment of a second assistant, the Ministry's attitude, supported by the Executive Councils' Association, is that the approval of the Medical Practices Committee is desirable in order to eliminate, as far as possible, the practice of "farming out," and that if the decision were left to the Executive Council it would hamper the efforts of the Medical Practices Committee to obtain an even distribution of doctors. The G.M.S. Committee's view is that Executive Councils, with their greater knowledge of local conditions, are more suited to make the decision than comparatively remote central organizations. Amending regulations will shortly be issued giving effect to the points upon which agreement has been reached.

GRANTS FOR TRAINING ASSISTANTS

In connexion with the Ministry's scheme of grants for training assistants, the Ministry was asked to consider giving some guidance to Local Medical Committees concerning factors which should be taken into account in considering applications from doctors for grants. The Committee was concerned at the situation which might arise if the number of trainers greatly exceeded the number of trainees. The Ministry agreed, and the Committee had an opportunity of discussing the draft of Circular E.C.L. 152 (Feb. 28, 1949) to Local Executive Councils giving the principal factors to be taken into account when considering applications for grants.

Subsequently, the scheme was examined by a special subcommittee with the object of suggesting improvements. The general conclusion reached was that the scheme as at present designed is primarily for the benefit of the trainee and should be regarded as such. Any financial benefit which the principal may hope to derive from the help given by the assistant (as suggested in the Spens Report) could and should be met in other ways, such as an adequate capitation fee. Other decisions reached were that appointments as "trainers" should be for a period of years and should not for the present exceed one year, and that a principal should not accept a trainee assistant who is liable for National Service during a period of training.

The scheme will be reviewed in the light of the experience of a year from its inception.

HEALTH CENTRES

The Committee continues to watch the position closely as plans for Health Centres develop, and Local Medical Committees have been asked to use their influence to prevent hasty establishment of undesirable types of Health Centre.

A special subcommittee has been set up to investigate the question of protecting the practices of doctors who consent to practise at such centres.

DENTAL SERVICES

Anaesthetics and X-ray Examinations

The cutting of the remuneration of dentists whose earnings exceeded £4,800 a year resulted in a tendency not to employ doctors for *x*-ray examinations and the administration of anaesthetics, as the fees for these services were included in the dentist's gross remuneration.

With regard to the amount of the fees payable for the administration of dental anaesthetics, the Ministry states that these fees apply also to dentists acting as anaesthetists, and must be related to the dentists' scale of fees. For this reason the Ministry cannot hold out any hope of an increase in the scale where a medical practitioner administers an anaesthetic. Joint representations with the British Dental Association are being made to the Ministry on this matter. The fees for dental anaesthetics are not affected by the recent cut of approximately 20% in dentists' remuneration.

Emergency Treatment following Dental Operations

The Ministry of Health has been asked to make provision for the payment of a fee to a doctor when he is called in to an emergency following a dental operation, the dentist not being available. It is considered that the fee should be not less than the dentist would receive for a similar service and should not come from the Medical Pool.

Whilst the Ministry's present view is that it is not legally possible to regard a doctor called in in such a case as the dentist's deputy, and therefore entitled to a fee under the dental scale, the Ministry has promised to give the matter further consideration.

Liaison with Dentists

The Committee has arranged an exchange of observers with the organization representative of the general body of dentists.

TREATMENT OF SEAMEN

Discussions were held with the Ministry of Health, the Shipping Federation, and the Protection and Indemnity Association as the result of which the Ministry prepared draft instructions to Executive Councils giving authority for whole-time medical officers of the Shipping Federation to be included in the medical list for the purpose of treating seamen as temporary residents. The Committee took strong exception to the draft instructions on the grounds that (*a*) a doctor should not be allowed to have his name on the medical list for the treatment of temporary residents only, and (*b*) it appeared that the Central Practitioners' Fund would receive no payment for these cases.

Subsequently, the Ministry recognized the Committee's objection to the inclusion of these officers in the Medical List for a limited purpose and agreed that it would be preferable to deal with the situation by means of a small allocation from the Central Pool. On the question of the augmentation of the Pool by reason of the arrangements for foreign seamen, the Department claims that, although seamen in ships laid up in ports were not included in the population figures, their omission is counterbalanced by the inclusion of persons for whom general practitioners are not at risk. The Committee cannot accept this suggestion, and the matter is being pursued with the Ministry.

TREATMENT OF MEMBERS OF H.M. FORCES ON LEAVE

The War Office suggested that officers and soldiers who fall sick on leave and who are obliged to seek treatment of civilian doctors might be treated as temporary residents under N.H.S. arrangements, the appropriate credits being added to the Central Pool. The Committee was not in agreement with this suggestion, and the War Office was so informed. The Ministry of Health has subsequently supported the Committee's view that there should be no change in existing arrangements.

FEES FOR EMERGENCY TREATMENT AND ANAESTHETICS

The Committee considered and approved the draft instructions and model forms for use by Executive Councils in connexion with claims for fees for emergency treatment and anaesthetics. Several minor amendments were suggested to and accepted by the Department. As in the past, Local Medical Committees may substitute their own scale of emergency fees for the scale suggested by the Ministry.

EMERGENCY TREATMENT OF SCHOOL-CHILDREN

The question of the emergency treatment of school-children has been explored with the Ministry of Health from the point of view that there are calls on the Local Practitioners' Fund for emergency fees without the patient's doctor being afforded an opportunity to attend. The Ministry of Education has been asked to co-operate by approaching teachers through local education authorities.

MAXIMUM NUMBERS ON DOCTORS' LISTS

It has been agreed that general approval of lists in excess of the prescribed maxima should be withdrawn, and that action might be taken to bring such lists within the prescribed maxima as soon as is reasonably practicable. No action should be taken in individual cases, however, until all the doctors' lists in the areas concerned have been cleared of duplicate names. Executive Councils have been advised that, as a first step, the doctor should be asked to refrain from accepting any more patients on his list until the total number is below the permitted limit.

MEDICAL TREATMENT OF OVERSEAS VISITORS

Counsel advised that section 33 of the National Health Service Act, which requires an Executive Council to arrange for the provision of medical services for "all persons in their respective areas," means that no qualification is required for taking advantage of the relevant arrangements other than that the person is in the area to which the arrangements relate. Overseas visitors are thus entitled to the benefits of the National Health Service during their stay in this country. The Ministry was asked to amend the Act so as to exclude such visitors from taking advantage of its provisions.

ACCOMMODATION FOR DOCTORS

The Committee's attention has been drawn to circumstances in which it appeared that an Executive Council could compulsorily acquire, at a sum arrived at under the Compulsory Acquisition Code, the property of an outgoing doctor, although in certain instances approval of payment at current market prices could be obtained. Legal advice was obtained on the position of the outgoing doctor under the Compulsory Acquisition Code, and an assurance was received from the Ministry that in all cases the Department is dependent upon acquisition by agreement. It appears that the Ministry is only empowered to pay a price arrived at under the Compulsory Acquisition Code. Treasury approval can be sought to pay an amount in excess of that prescribed by the Code.

POSTAGE ON OFFICIAL COMMUNICATIONS

The opinion expressed by the Annual Conference (Minute 82), that the appropriate method of reimbursing doctors for postage on documents to Executive Councils is by the issue of official

franked and addressed envelopes, has been discussed with the Ministry of Health. The Ministry's view is that postage is a proper charge on a doctor's practice expenses and that arrangements for franking envelopes are not justified.

FRIVOLOUS OR UNJUSTIFIED EMERGENCY CALLS

The Ministry has been asked to reintroduce rules for the conduct of patients which were in operation under the National Health Insurance Act, with disciplinary machinery to be used in the event of non-observance. This would involve a substantial revision of the medical card.

MEDICAL CARD

A number of suggestions for the amendment of the medical card have been sent to the Ministry. The Ministry of Health has agreed to the suggestion (Minute 92 of the Annual Conference) that in appropriate cases a person's medical card shall indicate that the holder is a dispensing patient. The former practice of stamping a large "D" against the person's name is to be continued.

EMERGENCY BED SERVICE

The Committee has given its support to a number of suggestions made by the London Local Medical Committee for improving the present emergency bed service. Immediate action is recommended in order to minimize the possibility of a breakdown during the coming winter. It has urged the necessity of making one official in each Hospital Management Committee area ultimately responsible for the admission of a patient to hospital.

TELEPHONE CHARGES

The Ministry was informed of the heavy cost of telephone charges now falling upon rural practitioners as a result of the National Health Service, and it was suggested that in respect of other than local calls a practitioner should be able to reverse telephone charges where a call is made to a hospital on behalf of one of his patients. It is understood that such a practice is in fact prevalent in some parts of the country. Examples of heavy telephone costs have been sent to the Ministry, which is investigating the possibility of adopting the Committee's suggestion.

SUPPLEMENTARY OPHTHALMIC SERVICES

The Committee is in agreement with the view of the Association's Central Ethical Committee that arrangements by industrial firms for the ophthalmic examination of employees under the National Health Service are undesirable.

PARTNERSHIP SHARES

The Committee was asked by the Medical Practices Committee for its views on the stage, if any, at which a junior partner should reach parity with his senior partner or partners in the division of the partnership. The Committee feels that the answer must depend on circumstances which vary greatly in different practices and different areas. Where, for example, a single-handed practitioner takes in a partner, there being a reasonable prospect of expansion of the practice, it might well be reasonable for parity in division to be reached in five or seven years. On the other hand, where a practitioner of 50 takes in a partner of 25 and there is no reasonable prospect of expansion or of an equal distribution of work and responsibility, it would be reasonable to defer the stage of parity for a much longer period if, indeed, it is ever reached. Again, where it is contemplated that a second junior partner may be taken in, the problem assumes quite a different complexion. The Committee, while anxious to give the Medical Practices Committee all possible help, is unable to recommend a particular formula, and regards the problem as one which must be examined in the light of each set of circumstances.

REPORT OF WORKING PARTY ON MIDWIVES

This report has been considered by the Committee jointly with the Public Health and Central Consultants and Specialists Committee, and their observations have been sent to the Ministry on behalf of the Association. The Committee's representatives were Drs. H. H. D. Sutherland (London), J. G. Thwaites (Brighton), and A. T. Rogers (Bromley).

Briefly, the Association supports many of the recommendations of the Working Party, but feels that those concerned should recognize that there is no acute crisis in the midwifery profession. Tribute is paid to the continuous efforts which have been made during the past twenty years by the Central Midwives Board, the College of Midwives, and individual tutors and matrons to develop the profession; and it is felt that the best results in the future will be achieved by fostering these existing agencies.

REGISTRATION OF BABIES

It has been suggested that form H.S.L., which is apparently issued to all persons registering the birth of a baby, should be amended by the inclusion of a reference to the parents' right to have the baby treated by a private medical practitioner should they so desire. It has also been suggested that the general phraseology of the form should be in the nature of advice rather than an instruction.

"COVERING" AN UNQUALIFIED PRACTITIONER

The question has been raised with regard to the position of a general medical practitioner who discovers that his patient is receiving treatment from an unregistered practitioner, with particular reference to the issue of certificates. A comparison with the old and new regulations relevant to the subject has been made and legal advice sought on this point.

SCOTTISH LOCAL MEDICAL COMMITTEES—TRAVELLING EXPENSES

The Committee was asked to consider a request from a Conference of Scottish Local Medical Committees that travelling expenses and subsistence allowances, where necessary, in attending meetings of Local Medical Committees should be paid from central funds. It is recognized that geographical conditions in some parts of Scotland impose a heavy burden on the funds of Local Medical Committees for those areas in meeting the travelling expenses of their members. It has been decided, therefore, that where it can be proved that the product of the usual levy for a Committee's expenses is not sufficient to meet claims for travelling and subsistence expenses consideration will be given to the possibility of making a grant to the Committee from the National Insurance Defence Trust.

GENERAL PRACTITIONERS' REFRESHER COURSES

The Ministry is arranging for the present scheme of post-graduate study for general practitioners to be supplemented by a new type of course, to be known as a "Special Short Course." It will consist of three half-day sessions at the week-end or during the week. The conditions of grant and procedure applicable to the longer courses will be the same, with the modification that a doctor may take a maximum of seven courses of three sessions (or any combination of such courses with the 11 session courses which does not exceed 22 sessions) in any year. The fee for the course will be paid by the Ministry direct, and travelling expenses and subsistence allowance may be reclaimed by the doctor, but it is not expected that any expenses for the payment of a locum tenens will be allowed for the short courses.

AN ETHICAL PROBLEM

The position in law appears to be that a doctor suitably qualified may have his name on two or more lists under the National Health Service—for example, as a general practitioner, an optician, or a pharmacist. The Committee is in agreement with the recommendation of the Association's Ethical Committee, endorsed by the Council, that this possibility is to be deplored on the grounds that it is beneath the dignity of the profession so to act and may promote unethical practices.

PURCHASE TAX ON MEDICAL RECORD FILING CABINETS

The Ministry was asked for assistance in securing the abolition of purchase tax on filing cabinets for medical records. The Ministry approached the Board of Customs and Excise, whose reply was that it had no authority to remit or refund purchase tax on equipment of this nature, and that there was no possibility of obtaining such authority. Not only are there administrative difficulties in giving preferential treatment to particular classes of purchasers, since purchase tax is charged at the wholesale stage, but a concession to doctors would make it impossible to resist other claims which would be regarded as equally strong.

INCOME TAX

The Board of Inland Revenue was asked to agree that medical practitioners who wish to do so should be allowed to pay income tax by quarterly instalments. The reply received was that the Board was unable to authorize any general arrangements for the collection of tax from doctors by quarterly instalments, but that Collectors of Taxes would be prepared to consider, on its merits, any case in which a doctor is unable to meet his tax liability on account of reduced earnings.

NATIONAL INSURANCE DEFENCE TRUST

The balance sheet and statement of expenditure and income of the Trust for the year ending Dec. 31, 1948, are being sent to every Local Medical Committee.

As Local Medical Committees are aware, the trustees of the National Insurance Defence Trust were the members of the Insurance Acts Committee for the time being in office. With the replacement of the Insurance Acts Committee by a new Committee of the B.M.A.—the General Medical Services Committee—it was hoped that by passing a formal resolution the funds of the N.I.D.T. could be transferred to a new Trust administered by trustees who would be the members of the new G.M.S. Committee. According to legal advice the obstacle to this is the fact that a trust, once formed, cannot hand over its assets to another body.

Leading Counsel's advice was sought as to the action which should be taken in the changing circumstances. This confirmed the advice already given—namely, that the funds of the existing N.I.D.T. could not be transferred to another body; and that in the circumstances it would be best to form a new Trust Fund which would eventually be the only one acting on behalf of general medical practitioners. The position, therefore, is that in the immediate future there will be two funds—the N.I.D.T. and the G.M.S. Defence Trust; that in any emergency the funds of both Trusts will, if necessary, be used for identical purposes, but in the meantime all payments within the objects of the Trusts will be met from the N.I.D.T. until such time as the moneys at its disposal are exhausted; and that no further contributions will be made to the N.I.D.T., all new contributions being credited to the G.M.S. Defence Trust. A new Trust Deed, inaugurating the G.M.S. Defence Trust, has been prepared and signed by the members of the G.M.S. Committee. Under this Trust Deed it is necessary for a sum of money to be placed at the disposal of the trustees to form the nucleus of the fund to be held on trust, and £50 has been voted from the N.I.D.T. for this purpose.

It should be clearly understood that the formation of the new Trust does not, in effect, change the guardianship of the money which has been subscribed over a number of years by doctors engaged in the late National Health Insurance medical service. It remains, as before, their money, and will be administered as such by the trustees, who are members of the Committee which has taken over functions of the old Insurance Acts Committee.

Consideration is now being given to the form of appeal for contributions to the new Trust.

The Trustees of the N.I.D.T. have undertaken to make available to the new British Medical Guild, which was formed by the Council of the B.M.A. in April, the sum of £500 to form the nucleus of the fund to be administered by the Guild. The Guild, the N.I.D.T., and the G.M.S. Defence Trust would, of course, work in close co-operation in any emergency involving members of the medical profession engaged in the National Health Service.

S. WAND,
Chairman, General Medical Services Committee.

SCOTLAND

(This Section deals with matters which have a Scottish aspect)

General Medical Services Subcommittee (Scotland)

Consequent upon the replacing of the Insurance Acts Committee by the General Medical Services Committee, the Insurance Acts Subcommittee (Scotland) has been succeeded by the General Medical Services Subcommittee (Scotland). For the time being this Subcommittee retained the constitution of the I.A.S.C., but recommendations have recently been made to and accepted by the General Medical Services Committee for modification of the constitution. The revised constitution allows each Local Medical Committee in Scotland to be directly represented on the Subcommittee by at least one member, with an increase in the number of members in the larger areas proportionate to the number of resident practitioners on the Executive Council lists, and provides for the inclusion in the Subcommittee of representatives of consultants and specialists and Public Health Medical Officers in Scotland.

The Subcommittee has appointed a Chairman's Subcommittee, with executive power, to act between meetings of the full Subcommittee; also a Rural Practitioners' Subcommittee to deal with matters affecting general medical practice in rural areas under the National Health Service, not specifically related to conditions in the Highlands and Islands. The formation of a Colliery Subcommittee to replace the former Colliery and Public Works Surgeon's Subcommittee (Scotland) is under consideration.

The question of the appointment of a joint subcommittee composed of representatives of the General Medical Services Subcommittee (Scotland) and the Central Consultants and Specialists Committee (Scotland) to consider the problems of general practitioners in relation to the hospital service is under consideration.

Chairman and Deputy Chairman

Dr. W. M. Knox and Dr. W. Jope were appointed Chairman and Deputy Chairman of the Scottish Subcommittee respectively for the session 1948–9.

Constitution of Local Medical Committees in Scotland

These committees were appointed in the first instance for an interim period, and the question of drawing up a model scheme of permanent constitution has recently been considered. Conditions vary so considerably in the different areas that it has not been thought advisable to adopt a model scheme applicable throughout Scotland. Instead a memorandum laying down general principles for the guidance of the Committees in drawing up their permanent constitution has been circulated.

Advisory Distribution Committee

The following were appointed as the representatives of the Scottish Subcommittee on the Scottish Advisory Distribution Committee: Dr. W. Jope (High Blantyre), Dr. W. M. Knox (Glasgow), Dr. A. Simpson (Hawick), and the Scottish Secretary.

Medical Advisory Committee

The previous arrangement in connexion with this matter has been continued—namely, that all the members of the General Medical Services Subcommittee are regarded as available for service on the panel of medical practitioners constituted under Regulation 11 (3) of the Medical and Pharmaceutical Service Committees and Tribunal Regulations (Scotland).

Part-time Services rendered to Local Authorities

The Subcommittee has discussed with representatives of the Scottish Local Authority Associations the circumstances under which fees to general practitioners shall be payable by Local Authorities for part-time services rendered, and the question

of what services are covered by the fees payable to such practitioners under the National Health Service. The matters discussed include periodic examinations of boarded-out children, visits to children's homes and reception centres, certification of lunatics, certification for non-attendance of children at school, examination under teachers' sick pay regulations, and the fee for the report in cases of immunization and vaccination. The comments of the Local Authority Associations on the views put forward by the Subcommittee are still awaited.

Circulation of National Formulary in Scotland

The Subcommittee has discussed with the Department of Health the desirability of the circulation in Scotland of the new *National Formulary*. Scottish tradition in medicine has been for doctors to write individual prescriptions in full rather than order standard prescriptions from a formulary, and this procedure is still favoured in Scotland. The new formulary is, however, recognized as being a great advance on any previous publication. Consequently no objection has been raised to its circulation by the Department of Health for Scotland, on the definite understanding that there will be no implied pressure on the practitioner to use it in his prescribing and that he remains free to use prescriptions devised by himself or obtained from any other source.

Prescription Form

The single sheet prescription book is the form at present in use in Scotland. Recently, at the request of the Department of Health, the Subcommittee has considered the question of reversion to a triplicate form, and has discussed the matter with representatives of the pharmacists, who are anxious to secure a return to the triplicate form. The Subcommittee has informed the Department that in its view, while pharmacists have established a case for the keeping of some form of record, this is primarily for their own use and only secondarily to cover certain situations which might arise in practice. Under existing conditions, when the practitioner is labouring under great difficulties, it would be inopportune to ask him to undertake what is not an essential duty.

Dispensing Capitation Fee in Scotland

Attempts have been made unsuccessfully to secure an increase in the Dispensing Capitation Fee in Scotland from 5s. to 6s. 6d. to bring it to the level of that paid in England and Wales. Dispensing costs have always been lower in Scotland than in England and Wales, this being due to more economical prescribing procedure. So far as it has been possible to ascertain the facts, it appears that under the National Health Service the rise in the dispensing cost in England and Wales has been correspondingly greater than the rise in Scotland. In these circumstances the Department of Health is not prepared to consider a claim for an increase in the dispensing fee, but has agreed that the matter shall be reviewed in the light of the first year's working and that the question of retrospective adjustment shall receive sympathetic consideration if it should be shown that the 5s. fee is inadequate. As in England and Wales, Scottish "dispensing" doctors have the alternative of being paid on a "cost per prescription" basis.

Training of Assistants Scheme

The Training of Assistants Scheme as approved for Scotland is on similar lines to that in operation in England and Wales. The constitution of the Selection Committee, however, is somewhat different. In Scotland there is so much variation in size between the Local Medical Committee areas that the English scheme is not practicable. Selection Committees have therefore been based on the Regional Hospital Board areas. The Selection Committee is composed of a lay chairman appointed by the Secretary of State (after consultation with the profession); general practitioners, the number varying from region to region, selected in consultation with the Local Medical Committees; a representative or representatives of consultants and a representative of the university of the Region, with a medical secretary.

Expenses of Local Medical Committees

In Scotland, as in England, the question of the means by which the expenses of Local Medical Committees are to be met has been the subject of serious concern, particularly in relation to the Highlands and Islands. Representations have been made to the Department of Health that travelling expenses and subsistence allowances of members of Local Medical Committees in the Highlands and Islands should be defrayed from some source other than the Practitioners' Fund. The Department of Health has made it clear that there is no possibility of additional money being made available to meet these expenses, and it has been suggested that the expenses should be made a charge on a central fund and distribution loaded in favour of those areas where the expenses are disproportionately heavy, as in the Highlands and Islands. The formation of a separate executive council for the Outer Isles, which is now under consideration by the Highlands and Islands Standing Advisory Committee of the Scottish Health Services Council, might, it is thought, ease the problem.

Inducement Payments: Procedure and Scope

The question of the scope of the Inducement Fund, and the procedure for application to the Fund in its relation to Scotland, is at the present time under consideration and discussion with the Department of Health.

Vacancies in Medical Practices

The question of the method of filling of vacancies in medical practices under the Scottish regulations, and the delay in filling of vacancies under these regulations, is also the subject of active consideration.

Telephone Charges in Rural Practices

The need for some special payment to rural practitioners in respect of telephone calls, in view of the increase in these calls which the general practitioner is now required to make under the National Health Service and in the cost of telephone charges, has been discussed on several occasions with the Department of Health. The problem is regarded sympathetically by the Department, but action is deferred pending the outcome of the discussions which are taking place with the Ministry of Health in London.

Dental Treatment given by General Practitioners to National Health Service Patients

The question of emergency dental treatment by practitioners in the Highlands and Islands and other rural districts in Scotland where ordinary dental facilities are not easily available has been discussed with the Department of Health. The Department thought that it would be possible to devise some satisfactory system of payment for emergency dental treatment given by medical practitioners from funds additional to those provided for general medical services. The Department promised to give further attention to the matter and has under consideration arrangements which will apply to the Highlands and Islands area.

General Practitioners and *X*-ray Facilities

The question of the direct access of general practitioners to *x*-ray facilities, without prior reference to specialists or surgeons at out-patient departments of hospitals, under the National Health Service has been the subject of discussion with the Department of Health for Scotland, and is now under consideration by the appropriate committee of the Scottish Health Services Council.

Range of Service: Treatment of Venereal Diseases

Representations by the Subcommittee that domiciliary treatment of venereal disease should be regarded as outside the practitioner's terms of service, and therefore subject to a fee, are at the present time under consideration by the Department of Health.

W. M. KNOX,
Chairman, General Medical Services Subcommittee (Scotland).

APPENDIX "A"

GROUPING FOR ELECTION OF 33 DIRECT REPRESENTATIVES TO THE GENERAL MEDICAL SERVICES COMMITTEE

Group	No. of General Practitioners resident in the Group (Jan. 1, 1949)	No. of seats on Committee
A.1 Fife—Lothians and Peebles: Edinburgh—Roxburgh, Berwick, and Selkirk ..	544	1
A.2 Aberdeen and Kincardine: Aberdeen Burgh—Angus: Dundee—Perth and Kinross — Orkney — Caithness — Sutherland—Ross and Cromarty—Inverness—Banff, Moray and Nairn—Shetland	570	1

APPENDIX "B"

STANDING ORDERS OF CONFERENCE OF REPRESENTATIVES OF LOCAL MEDICAL COMMITTEES

(1) **Annual Conference of Representatives of Local Medical Committees.**—The General Medical Services Committee shall convene each year a Conference of Representatives of Local Medical Committees. The Conference shall ordinarily be held in the month of June.

(2) **Special Conference of Representatives of Local Medical Committees.**—A special Conference of Representatives of Local Medical Committees may be convened at any time by the General Medical Services Committee and shall be convened not later than one month after the requisition of not less than 20 Local Medical Committees, the period of one month being modified only by agreement of the Committees making the requisition.

(3) **Members of Conference.**—The Conference shall be composed of representatives of Local Medical Committees and of members of the General Medical Services Committee and of its Subcommittees.

(4) **Appointment of Representatives.**—The Local Medical Committee of each area in England, Scotland, and Wales is entitled to appoint one representative to every 350, or part of 350 above each completed 350, upon the Medical List of the area on Jan. 1 immediately preceding the Annual Conference. Each Local Medical Committee in Northern Ireland and the Central Practitioners' Committee of Northern Ireland shall be entitled to appoint one representative to attend the Conference.

(5) **Eligibility of Representatives to Conference.**—All representatives shall at the time of their election be medical practitioners and members or officers of a Local Medical Committee.

(6) **Tenure of Office of Representatives.**—The representatives elected to act at the Annual Conference shall continue to hold office until the commencement of the succeeding Annual Conference, unless the General Medical Services Committee is notified to the contrary by any Local Medical Committee concerned.

(7) **Procedure as to Seconding Motions or Amendments.**—No seconder shall be required for any Motion, Amendment, or Rider submitted to the Conference by the General Medical Services Committee or by a Local Medical Committee. All other Motions, Amendments, or Riders, after being proposed, must be seconded.

(8) **Time Limit of Speeches.**—A member of the Conference moving a resolution shall be allowed to speak for 10 minutes, and with this exception no speech shall exceed five minutes.

(9) **Reducing Time Limit.**—The Conference may at any period reduce the time to be allowed to speakers, whether in moving resolutions or otherwise.

(10) **Voting.**—Save as provided in Standing Orders (14) and (17), only representatives of Local Medical Committees shall be entitled to vote.

(11) **Mode of Voting.**—Voting shall be by show of hands unless a formal division is demanded by 20 Members of the Conference, signified by their rising in their seats, in which case the names and votes of the Members present shall be taken and recorded.

(12) **Rules of Debate:**

(*a*) A member of the Meeting shall stand when speaking and shall address the Chair.

(*b*) Every member shall be seated except the one who may be addressing the Meeting, and when the Chairman rises no one shall continue to stand, nor shall anyone rise, until the Chair is resumed.

(*c*) A Member shall not address the meeting more than once on any motion or amendment, but the mover of the resolution or amendment may reply and in his reply shall strictly confine himself to answering previous speakers and shall not introduce any new matter into the debate.

(*d*) No notice of motion or amendment to any motion shall be considered until a copy of the same with the name of the

proposer and seconder has been handed in writing to the Chairman.

(*e*) Whenever an amendment to an original motion has been moved and seconded, no subsequent amendment shall be moved until the first amendment has been disposed of, but notice of any number of amendments may be given.

(*f*) If an amendment be carried, the amendment or motion, as amended, shall take the place of the original motion, and shall become the question upon which any further amendment may be moved.

(*g*) If it be proposed and seconded that the meeting do now adjourn, or that the debate be adjourned, or that the meeting do proceed to the next business, or that the question be now put, such motion shall immediately be put to the vote without discussion, except as to the time of adjournment, provided always that the Chairman shall have power to decline to put to the meeting the motion that the meeting do proceed to the next business or that the question be now put, and that the mover of any motion or amendment shall have a right of reply before the question is put. A two-thirds majority of those present and voting shall be required to carry a proposal "that the Meeting proceed to the next business" or "that the question be now put."

(13) **Rescission of Resolution.**—No motion to rescind any resolution of the Conference shall be in order at any subsequent Conference unless notice is given by the General Medical Services Committee or by a Local Medical Committee. In the latter case notice must be received by the General Medical Services Committee not less than two months before the date of the Annual Conference and not less than one month before a Special Conference.

(14) **Election of Chairman:**

(*a*) At each Annual Conference a Chairman shall be elected who shall hold office from the termination of that Conference until the termination of the next following Annual Conference. All members of the Conference shall be entitled to vote.

(*b*) Nominations shall be handed in, in writing, before noon of the first day of the Annual Conference, the election, if any, being held during the following afternoon session.

(15) **Election of Six Members of the General Medical Services Committee:**

(*a*) For the purpose of this election "Representative" shall be defined as the duly appointed representative of a Local Medical Committee, or, in his absence, the Deputy duly appointed in his stead, in attendance at the meeting.

(*b*) Nominations may be made only by representatives, and a representative may make not more than one nomination. Any registered medical practitioner actively engaged in practice as a general medical practitioner under the National Health Service Act, whether a member of the Conference or not, is eligible for nomination.

(*c*) Nominations must be handed in on the prescribed form before noon of the first day of the Annual Conference, the voting, if necessary, taking place during the afternoon session. Only appointed representatives or deputy representatives in attendance at the meeting are eligible to vote.

The General Medical Services Committee shall be empowered to fill casual vacancies occurring among the elected members.

(16) **Returning Officer.**—The Secretary of the Association, or in his absence one of the Deputy Secretaries, shall act as Returning Officer in connexion with all elections.

(17) **Conference Agenda Committee.**—(*a*) The Agenda Committee shall consist of the Chairman of the Conference, the Chairman of the General Medical Services Committee, together with three members elected by the Conference. The duty of the Agenda Committee shall be to settle the order of the Agenda of the Conference and to report: (*b*) Nominations for the Agenda Committee must be handed in on the prescribed form before noon on the first day of the Annual Conference, the voting, if any, taking place during the afternoon session. Any member of the Conference may be nominated for the Agenda Committee and all members of the Conference shall be entitled to vote in the election for this Committee.

(18) **Dinner Committee.**—At each Annual Conference there shall be appointed a Conference Dinner Committee, formed of five members of the Conference, to take all necessary steps to arrange for a Dinner to be held at the time of the following Annual Conference, to which the members of the General Medical Services Committee, amongst others, shall be invited as guests of the Conference.

(19) **Suspension of Standing Orders.**—Any one or more of the Standing Orders may be suspended by the meeting, provided that three-fourths of those present and voting shall so decide.

(20) **Quorum.**—No business shall be transacted at any Conference unless there be present at least one-third of the number of Representatives appointed to attend such Meeting.

DISPENSING ERRORS

Commenting on a newspaper report that nearly one bottle of medicine in four prescribed under the National Health Service is wrongly dispensed by chemists in the Service, the Ministry of Health states that in fact just under 10% of the cases examined have been referred to the appropriate committee of the executive council to consider whether there are any grounds for disciplinary action against the chemist.

Test analyses of drugs and dressings were started on April 1. During the quarter ended June 30, 1,753 samples were tested in England and Wales; of these the results of 748 were not known by June 30. Of the remaining 1,005 cases no action was found necessary in 909—i.e., just over 90%.

It is too early to say whether disciplinary action will be taken in the remaining cases, but in 1932, under National Health Insurance, out of 389 cases referred to the appropriate committee of the insurance committee only 227 resulted in disciplinary action. Under N.H.I. before the war disciplinary action was necessary in about 5% of cases, and consisted either in a warning or in withholding part of the chemist's remuneration.

WAR PENSIONS

TIME LIMIT FOR REVIEW

The Minister of Pensions has announced that applications for the review of cases by Special Review Tribunals cannot be accepted after Nov. 30.

The Special Review procedure applies *only* to persons whose claims arose out of the 1939 war and whose appeals were disallowed by Pensions Appeal Tribunals before Aug. 1, 1946.

Special Review Tribunals were set up in 1946 because certain judgments in the High Court in England and the Court of Session in Scotland had affected pension law. It was felt that persons whose appeals had been disallowed before those judgments had been given should have the right to have their cases reconsidered.

SICKNESS BENEFIT CERTIFICATES

Draft regulations that came into operation on Aug. 4 allowing medical certificates for sickness benefit to be given at longer intervals in cases of prolonged illness were reported in the *Supplement* of Aug. 13 (p. 80). The Ministry of Health has given further information about them, which we reproduce here.

In the light of the past year's experience the Ministry of Health and the Ministry of National Insurance have been examining proposals for reducing the doctors' certification work by extending the intervals of time at which Special Intermediate Certificates may be given in support of claims to sickness benefit in cases of prolonged incapacity. An amendment has now

been made to the Medical Certification Regulations with the following effect:

(i) Special Intermediate Medical Certificates (Form Med. 3) may now be given for a maximum period of thirteen weeks (instead of the former eight weeks) where the incapacity has already lasted for six months and the doctor is of the opinion that it would last at least a further thirteen weeks.

(ii) A Special Intermediate Certificate for any period for which the doctor considers the incapacity will last up to a maximum of thirteen weeks (or four weeks when the incapacity has lasted four weeks but less than six months) may be given even though the doctor intends to see the patient at more frequent intervals.

The amending regulations, which have been made provisionally (pending their consideration by the National Insurance Advisory Committee) came into operation on Aug. 4, 1949.

Where the doctor has given a certificate for thirteen weeks in accordance with these regulations it is intended that, as soon as the necessary arrangements can be made, the patient should normally receive from the Ministry of National Insurance a sickness benefit order book (similar to a pension order book) containing thirteen weekly orders, which can be cashed at the post office of his choice. Towards the end of each book there will be a slip reminding the patient that he must ask the doctor for a fresh medical certificate at the end of the thirteen weeks if his incapacity is continuing. If the patient recovers before the period of the order book expires the doctor should issue a final certificate.

Form Med. 3 is being amended to correspond with the new regulations, but as it will take some considerable time to get a sufficient supply of the new certificates into the doctors' hands it has been agreed that the existing stocks of Form Med. 3 may be used for giving thirteen-week certificates under the new regulations. Any Form Med. 3 completed on or after Aug. 4 will be read as if it had been amended in accordance with the regulations even though the actual amendment is not made on the certificate by the doctor. The amendments are:

(*a*) the deletion of the words "your incapacity is of such a character that it will be unnecessary to see you for the purpose of treatment more frequently than once in..... weeks, and";

(*b*) the substitution of the words "at corresponding intervals" for the words "at the intervals stated above";

(*c*) the substitution of the word "certification" for the word "attendance."

In order that persons whose incapacity has already lasted six months and is likely to continue may have the full advantage of the new method of paying sickness benefit by quarterly order books it is hoped that, subject to any medical considerations affecting individual patients, doctors will co-operate by giving thirteen-week certificates in all suitable cases.

The new regulations do not of course affect the doctor's obligation to see the patient for treatment as often as may be necessary, and in particular to see the patient each time a certificate is given.

PAY OF COLONIAL MEDICAL OFFICERS

Good progress is being made in the negotiations with the Colonial Office on this subject. A working party of officials from the Colonial Office and from B.M.A. House has almost completed the task of evaluating the adjustments which have to be made to the Spens salaries in order to take account of the many factors peculiar to the Colonies—e.g., income-tax, pensions, etc.

REFRESHER COURSES FOR G.P.s

Financial assistance is now available for special short courses consisting of three half-day sessions at the week-end or during the week—in the latter case either during the same week or spread over several weeks.

A general practitioner in the Service may take a maximum of seven courses of three sessions in a year or any combination of such courses with the 11-session courses which does not exceed 22 sessions. The conditions are otherwise the same as those described for the courses reported in the *Supplement* of Oct. 30, 1948 (p. 149).

INFLATION OF LISTS

In order to try to reduce the risk of inflation of general practitioners' lists the Ministry of Health has decided, after consultation with the General Medical Services Committee, that Form E.C.1 should not be made as freely available as at present. The ready availability of the form encourages people to use it when changing their doctor, and there is a possible risk of inflation if it is not completed fully or accurately.

Stocks will be withdrawn from post offices, and the Minister has asked executive councils to withdraw any substantial stocks from libraries and not to issue further supplies of them. In future the form will be obtainable only from executive council offices, from doctors' surgeries, and (on the registration of a birth) from the Registrar of Births.

When a patient dies his medical card should be handed to the Registrar of Deaths.

PRIORITY OPHTHALMIC ARRANGEMENTS

Priority labels are attached to prescriptions for patients whom the optician considers require urgent treatment. The manufacturer separates these from the rest of the order and deals with them as rapidly as possible. Since only a limited number of prescriptions can be dealt with in this way, the Ministry of Health has asked that the priority labels should be reserved for cases of the following types:

(1) Cases of progressive defect in children, or in which delay in the supply of glasses is likely to result in serious deterioration of vision, especially short-sighted children, children with certain types of squint, and children at schools for the partially sighted.

(2) Cases in which the person concerned would be totally unable to carry on everyday duties or normal work without glasses.

SPECIAL DRUGS

The Ministry of Health has issued the following list of drugs, reagents, and appliances for the supply of which doctors receive payment over and above their capitation fees. Suggestions for amendments to the list are being considered.

Drugs

Allergenic protein preparations. Antihistamine agents. Organic arsenic compounds used for the treatment of venereal disease (when supplied to patients for whom a supply is not made gratuitously available by any public authority). Bismuth compounds, for parenteral injection. Colloidal preparations for parenteral injection. Desiccated stomach, extracts of stomach, and the active principles of stomach supplied for the treatment of pernicious anaemia and of disseminated sclerosis. Emetine and its salts, for parenteral injection. Ethisterone. Ethyl chloride. "Folic acid." Hormone preparations, for parenteral injection. Gold compounds, for parenteral injection. Insulin. Liver extract and the active principles of liver, supplied for the treatment of pernicious anaemia and of disseminated sclerosis. Mercury and mercurial compounds, for parenteral injection. Mersalyl suppositories. Oxygen. Penicillin and preparations of penicillin. Peptone preparations, for parenteral injection. Phenytoin sodium. Phthalylsulphathiazole. Protein sensitization test solutions. Sclerosing agents for the injection treatment of varicose veins. Sera (when supplied to patients for whom a supply is not made gratuitously available by any public authority). Succinylsulphathiazole. Sulphadiazine and methylsulphadiazine. Sulphadimidine. Sulphathiazole. Toxins, anti-

toxins, and vaccines (when supplied to patients for whom a supply is not made gratuitously available by any public authority). Vitamin B_{12} for parenteral injection.

Reagents

Benedict's solution (qualitative) and Fehling's solution, when required for the regulation of the treatment of diabetes.

Appliances

Atomizers, hand operated. Bandages: elastic adhesive, elastic web, zinc paste. Breast relievers. Urethral catheters: gum-elastic, soft rubber, and lubricant for use therewith. Colostomy belts and parts thereof and repairs and replacements thereto. Douches, with rectal and vaginal fittings. Elastic anklets, knee leggings, knee stockings, knee-caps, leggings, stockings, thigh knee-caps, thigh leggings, thigh pieces, thigh stockings. Hypodermic needles and hypodermic syringes, when required for self-administration of insulin or adrenaline. Ice bags: check sheeting, indiarubber. Inhalers: earthenware (Nelson), Burney Yeo. Splints: simple splints, wooden, metal, or plastic, for upper and lower limbs; Gooch splinting; Kramer splinting. (All other splints will be supplied through the hospital service.) Sputum flasks. Suprapubic belts and parts thereof and repairs and replacements thereto. Trusses: femoral, inguinal, scrotal, umbilical. Vaporizers, as specified in the Drug Tariff.

Questions Answered

Private Patients' Use of N.H.S.

Q.—*Can a patient who is not registered with a practitioner under the N.H.S. (a) have the right to a specialist under the domiciliary scheme, (b) partake of the maternity medical service without payment?*

A.—(a) Yes. (b) Yes.

Certificates for Corsets

Q.—*What is the present state of the regulations concerning the provision of corsets and brassieres? By this I mean by purchase and not through hospitals. General practitioners know that it is no longer necessary for one of a certain number of named disabilities to be specified in order to qualify for one of these garments, but one is constantly being told by the manufacturers or their agents that they cannot be supplied at all except under medical certificate. Is this true or not? Or, alternatively, does the medical certificate exempt the purchaser from purchase tax?*

A.—A medical certificate from the patient's general practitioner is not necessary for the purchase of corsets from a private manufacturer. A medical certificate is still necessary if the patient wishes to claim exemption from purchase tax on the article. Discussions are now taking place with the Ministry of Health and H.M. Customs and Excise on this latter point.

Partner's Option

Q.—*I am a partner in a firm of three—A, B, and C. Under our partnership agreement made in 1946, C has an option to buy a further 22nd share from A on Oct. 1, 1949. C gave notice to A that he wished to avail himself of this option on June 30, 1949. A has taken advice on the matter and states that there can be no reallocation of the partnership shares until the Amending Bill to the N.H.S. Act becomes an Act. Is this so?*

A.—There is no reason why Dr. C should not exercise his option. Provision is made in the Bill for this part of the Act to be retrospective. Section 4 (1) reads as follows:

"*Retrospective effect of Section 1 of the Act.*

"4. (1) Section 1 of this Act shall apply in relation to rights and obligations which were exercised or performed, or were required to be exercised or performed, on or after the appointed day and before the passing of this Act, under an agreement to which that section applies. . . ."

Section 1 of the Bill was published in the *Supplement* of May 21 (p. 274).

Income Tax on Hospital Salary

Q.—*I note in the Supplement of June 25 (p. 357) a question and answer on the subject of superannuation for assistants. In the substance of the question it is stated that the amount deducted from the salary of the assistant in respect of his living in is allowable as an expense for income tax purposes. Is this the case with hospital residents? I have just been informed that tax is to be deducted from my salary and also from my residential emoluments.*

A.—The money value of any residential emoluments received by a practitioner engaged in the hospital and specialist service is assessable for superannuation purposes. The position as regards income tax depends upon the actual terms of the contract. If the contract provides for the payment of a salary of, say, £500, with, in addition, the right to free board and lodging (reckoned for superannuation purposes at £100), only the £500 is taxable. If on the other hand the contract is for a salary of £600, out of which £100 is deducted for board and lodging, then the whole £600 is regarded by the income-tax authorities as taxable.

Retrospective Pay

Q.—*At the beginning of this year I was appointed to the post of resident medical officer to a hospital for a period of six months at a salary of £350 p.a. I reapplied for the same position in June, and was reappointed for the second half of the year. My status has now been defined as that of a registrar for purposes of remuneration, and my salary accordingly increased to £775 p.a. Am I eligible for back pay from Jan. 1, 1949?*

A.—It is laid down in the explanatory memorandum issued by the Ministry on the Terms and Conditions of Service of Hospital Medical Staff (para. 91 (5)—Retrospective Application. Senior Registrars, Junior Registrars, and House Officers) that the posts which an officer has held from time to time since the appointed day should be reviewed and classified in accordance with the new grading, remuneration then being adjusted retrospectively. Therefore, if the medical officer in question has held the same post and carried out the same duties from January, 1949, it would appear that he is entitled (upon the introduction of the new terms of service) to payment of salary in accordance with his recent grading retrospectively to the beginning of the appointment.

Postgraduate Students from the Dominions

Q.—*What is the position of postgraduate students from the Dominions holding junior house appointments in this country, such students having held one, two, or more house posts in their own country, and also perhaps having had war service? Are these previous posts taken into consideration in assessing the salary, or must these doctors accept the minimum salary (£350 p.a.) for the first post held in England irrespective of their previous experience in their own country?*

A.—It is understood that, in the case of Dominion practitioners obtaining junior house appointments under the National Health Service in this country, similar posts previously held in other parts of the Commonwealth may be taken into account in fixing the salary of the appointment.

Resident Staff Under N.H.S.

Q.—*Will you please clear up a few points regarding the position of resident staff under the National Health Service? The vagueness lies mainly in the junior registrar posts. What qualifications or experience will be required for such a post, or will each advertisement stipulate the requirements? Secondly, what happens to a medical officer after his third hospital post? Does he continue on the £450 grade till he eventually succeeds in obtaining a junior registrar post, or will he be entitled to further increments? The difference in salary is £220—rather a high rise if there are no intermediate grades.*

A.—There are no criteria for the appointment of registrars (trainee specialists) in the terms and conditions of service other

than the minimum period of qualification which will normally be required—i.e., in the case of a junior registrar not less than one year's experience after registration; in the case of a registrar not less than two years' experience; and in the case of a senior registrar not less than four years. In practice each employing authority will stipulate the qualification and experience required, and the position will be very much the same as heretofore. Practitioners who have completed junior hospital appointments and who intend to specialize will seek higher posts which provide the necessary training and experience in open competition with their colleagues. A salary of £450 is payable for the third *and subsequent* house appointments, and an officer holding such an appointment will not receive any higher salary until he is successful in obtaining a registrar appointment or a post as junior hospital medical officer.

HEARD AT HEADQUARTERS

Hospitals and the Public

The first public meeting—in London, at all events—of a hospital management committee since the National Health scheme came into operation was held in Chelsea the other evening, and very interesting it was. The Chelsea group of hospitals is one of 50 groups under the control of the South-west Regional Hospital Board. The meeting was attended by the Mayor and the local Member of Parliament, and short accounts of their work were given by the chairman of the committee, the secretary, and the medical superintendents of the hospitals in the group. The beds available to the public in the three ex-council hospitals and the one ex-voluntary hospital which make up the group are considerably fewer than in 1939, but there has been a great increase in the number of operations performed and the radiological and pathological examinations undertaken, and an enormous multiplication, by nine or ten times, of out-patient attendances. The general tone of the meeting was one of optimism. The heavy cost of hospital services was fully recognized, but the public was assured that if hospital management committees had full control over administration there would be no waste. It seems an excellent idea to have such annual public meetings, alike to give the public information which they have a right to receive and to stimulate interest in hospitals, which is tending to flag since voluntary work diminished.

Horticultural Health Service

A doctor sends us the following letter that he received from a patient: "Dear Dr. ——, I want to have the electric current in the house. I think it will be healthier in this *little* house. I cannot grow bulbs very well indoors, and cut flowers do not last because of the gas. I believe perhaps the gas has a bad effect on myself. When I applied to the electric office I was told I must get a doctor's certificate. Will you please supply this. Also, will you please give me a certificate for new teeth. I have had these for years and cannot get the lower set in now. I require both top and bottom."

NEW ZEALAND MEDICAL SERVICE

Mr. E. W. Maples, LL.D., has written an interesting pamphlet on "Social Security Services in New Zealand" after an eight weeks' visit to the country. He compares the health services there with those in Britain, and emphasizes that the New Zealand method of paying doctors a fee for each service should not be adopted in England. He considers that, as in New Zealand so in England, the pressure on the doctor, which can be satisfied only too easily by prescribing drugs, is likely to increase materially. "The only remedy that seems possible is that patients, other than those in hospital, should be required to make some part payment of the cost, subject to the issue of free drugs to people suffering from illnesses like diabetes, and to repayment, to those on the poverty line, of the sums paid." He believes that the present scheme in New Zealand provides little or no encouragement to the individual doctor to gain further experience or to increase his skill. The pamphlet is obtainable from the author at 59, Bodenham Road, Hereford, if a stamped addressed envelope 9 in. by 6 in. is sent.

Correspondence

Position of Registrars

SIR,—I should like through the medium of the *Journal* to draw attention to the unsatisfactory position of a number of registrars throughout the country. There are on the staff of a proportion of hospitals registrars appointed before July 5, 1948, as honorary registrars. Some of these have held their posts for a year or two prior to the inception of the National Health Service Act and wait for vacancies on the medical or surgical staff in the ordinary course of events. During the tenure of their appointments the majority have worked hard, become integrated in the team work of their hospitals, and have earned the confidence and approbation of their seniors. These latter were, in the normal course, prepared to support the candidature of such registrars when a vacancy occurred on the hospital staff, in which appointment they exercised considerable influence.

With the inception of the new Act the staffs of the hospitals lost their influence over such appointments, and these are now made on the recommendation of a regional appointments committee to the regional hospital board. This committee contains two representatives only of the staff of the affected hospital out of seven members. The remaining members are appointed from outside the hospital group affected. It is true that these remaining five may give due attention to the opinion of the local members, but in effect appointments are liable to be, and no doubt are, made on paper records plus a short interview, and in these circumstances the local registrar is placed at a serious disadvantage.

Conceive the position of a registrar in the provinces who has held such a post for three years or more, who has been reasonably assured of appointment to a vacancy on the staff which he has known will be due to occur, and who has neglected opportunities of appointment elsewhere because of the local loyalties and associations he has formed during his period of probation. The vacancy occurs; sixty or seventy applications are received. Many of these come from younger, more recently qualified applicants, who have been acting as first assistant or as registrars at their teaching schools. Is it fair that a young man of this type should be appointed in preference to the local registrar who has been serving an apprenticeship the hard way for several years? I maintain, Sir, it is not fair.

A committee of cold-blooded assessors, diluted only by two in seven who have intimate knowledge of the work of the local candidate, cannot take into consideration any but the cold facts of qualifications and testimonials submitted to them. Many of the candidates from teaching centres will have the backing of their respective august chiefs, and these latter will have had opportunity to use their influence with the members of the committee from London or the university centre involved, to whom they will be well known. Indeed, they may even themselves be members of the appointments committee. In such circumstances the voices of the local members of the committee will be but faintly heard.

I feel that these committees should give very great weight, and indeed priority, to the opinion of the local members, who will have intimate knowledge of the *abilities* of one candidate at least.

Finally, Sir, what encouragement will this method of appointment give to future registrars? Can they be expected, especially in the provinces, to give unsparing loyalty and hours of overtime as they do at present, when the chances of their appointment to any vacancy which may occur are so nebulous? There appears to be an increasing tendency to appoint more and more registrars while making no provision for their future advancement by the creation of fresh specialist posts.

However, the future must care for itself. The position of the registrar is not quite the same as that of the honorary registrar appointed before the Act, whose case I am attempting to plead.—I am, etc.,

Plymouth. CYRIL F. MAYNE.

Telephone Duty

SIR,—Dr. E. Thomson (*Supplement*, July 16, p. 51) has referred to the telephone responsibility under the N.H.S. contract of service, and states that a doctor is responsible for the reception and forwarding of urgent telephone messages from his patients at any hour of the day or night.

I can remember no reference in the Act or in any contract that a telephone has to be a necessary equipment of the doctor's house. It is true that one's telephone number is requested on the executive council's form, but it is not a compulsory item. There is no legal obligation for a doctor to have a telephone at all, and if he wishes to run his practice without such an instrument I understand that he is at liberty to do so. I am informed there is no legal obligation for arrangements to be made to always have a continual telephone service any more than there is an obligation that the doctor's house shall never be left empty for a few hours.

As a country doctor without domestic help, either of such obligations would prevent me from ever going out with my own wife. A pad and pencil left outside the front door for visits or some such similar facility for messages is helpful, but again is not obligatory.

If desired, a telephone can be disconnected, and a doctor is free to go to those visits requested by letter or messenger only. Such a position is not very practical, but that is the position as I am led to understand it, and if true it should be known more widely.

I understand that a telephone call *once answered* does involve liability, but not otherwise.—I am, etc.,

Birmingham. E. J. JENKINS

Doctors and Dentists

SIR,—It is stated that for the first year of the Health Service in the Manchester area the average amounts paid approximated to about £3,400 per dentist and £1,280 per doctor in the Service. The value in terms of money of the dentist to the scheme is thus in round figures considered to be just under three times the value of the doctor's services. Are practising doctors as a body satisfied that this should be so?

Before the health scheme started it was generally conceded that the great responsibilities and exacting hours and duties of the average physician called for better rewards than those of the average dentist. One does not wish to express an opinion on the adequacy or otherwise of the average dental remuneration, but it is surely obvious to any fair-minded individual that the medical remuneration is hopelessly out of proportion to the duties involved.

One may take the Manchester figures as fairly representative of the industrial areas of the country. Let us remember that the doctor must keep up a 24-hour-day service in the home with the very considerable expense of keeping a car on the road every day of the year and a telephone and door serviced.

The dentist can manage very nicely without car or telephone except for his own personal convenience, and there is no night work. Let me put this in more concise form.

	Doctor	Dentist
Training	Long and arduous	Not so long or so arduous
Expenses	Considerable	Not so great
Hours of service	24-hour day	Ordinary daily hours—no night work
Car and travelling expenses	Essential	Unnecessary
Telephone	Essential	Convenient
Private practice	Practically eliminated	Still very considerable and lucrative
Practices	Confiscated. Appreciation—nil	Still retained with consequent house. Capital value appreciation
Servicing in the house of door and telephone	24-hour service daily	Not necessary
Holiday locum	Necessary	Unnecessary
Average income: Before scheme	1·25	2·65
After scheme	1	1
Treatment of dental haemorrhage	No extra fee	Special fee
Prospects	Pretty grim	Never brighter

And so you see the dentist has the advantage in every conceivable way.

One would imagine that the pay of chemists and opticians under the scheme is far above that of the doctors also. And yet we are the cornerstone of the whole edifice. For just how long are we willing to value our services at a pin's fee? Is it that the sacrificial role of Cinderella with least money for most work appeals to the self-abasing temperament of the long-suffering general practitioner?

The Minister of Health, possibly with good reason, appears to have a very poor opinion of the efficacy of the B.M.A. as a negotiating body (Committee stage of Amendment Bill). One can only hope that the B.M.A. will take steps to convince him without delay that nothing less than average remuneration totalling 25% above average dental remuneration will do for us. And let this happen before the inevitable plea of financial stringency is hurled at us. Remember, the dentists did not have their practices confiscated. What an asset now! Unity in the profession is of paramount importance. Without it we are lost. One would suggest that the local secretaries of the B.M.A. should be asked to make it their business to contact every G.P. in their area and that answers should be sought on these questions: (1) Are you satisfied? (2) Are you willing to withdraw from the scheme if advised so by the B.M.A.? It is obvious that local unity must be attained in this.

Whom the gods wish to destroy they first make mad, it is said. Is it that the medical profession (G.P. section) is in imminent danger of destruction? The labourer is worthy of his hire. We do not object to the dentists' being the spoilt darlings of the scheme. What we do object to is filling the role of poor relation. The doctors have to live as well as the dentists. The role of the big mug is a poor one as a permanency.

Dentists £3,400 per annum—doctors £1,280: it makes one gasp.—I am, etc.,

Manchester. K. V. DEAKIN.

Expose Defects

SIR,—The nation is passing through a crisis, and therefore a state of national emergency must exist. The National Health Service cannot expect to enjoy a separate existence in the face of the national emergency. It must take its place alongside all other vital national institutions.

Just as food is rationed to the bare necessities of life, and housing is restricted to a minimum, so, too, the Health Service must be restrained within medical and surgical necessities and essentials and the national facilities available.

It is now a year since the new Health Act first came into operation, and already its more glaring defects and shortcomings, both professional and economic, must have come to light. That the Act would be exploited was inevitable in view of its framework, but the extent to which it can be exploited must by now be exposed.

Members of the medical profession above all are in a position to fully appreciate these defects, shortcomings, and exploitations, and to gauge their full extent and gravity. They, above all, are in a position to adequately set them out and to suggest the remedies.

A possible withdrawal from the Service is said to be even under consideration. But here the issue would appear to be not entirely free from prejudice and personal grievances, many of which are common to everybody to-day. Would it not be more expedient if the profession were first of all to state a case on the disclosed defects, shortcomings, and exploitations of the Act, and have it laid if necessary before Parliament, at the same time claiming their just and undeniable right to the responsibility of declaring their remedies?

From the time a National Health Service was first mooted it was obvious that any such scheme could never be successfully implemented without the closest co-operation of the medical profession in both an executive and advisory capacity. That the Ministry of Health and Parliament may not have realized this does not relieve us of our responsibility.—I am, etc.,

New Buckenham, Norfolk. R. G. BLAIR.

Personality, education, diligence, knowledge, and clinical ability are conceded to the local consultants. Against this the appointing committee has no personal knowledge, as the old idea of interview has been abandoned, and the committee is probably a hundred miles away, out of reach of local opinion. As individual doctors these selectors would hesitate to risk a patient's life by prescribing by post; there seems no more justification for their actions here, with a professional life at stake.—I am, etc.,

Bournemouth. P. P. MCKINNEY.

The Maternity Service

SIR,—I have received my copy of the statement issued by the Standing Maternity and Midwifery Advisory Committee of the Central Health Services Council (*Supplement*, Aug. 6, p. 74). It only confirms the gross defect in the maternity medical service scheme, which was obvious before it began to operate.

The conscientious family doctor who joined the Service has continued to do his maternity work exactly as before. On the other hand, it seems (*vide Supplement*, April 23, p. 248), some doctors have booked far more cases than before with the deliberate intention of doing the minimum of work for the maximum number of flat-rate fees. They have made a racket of the thing. This is not surprising; the regulations invite it.

Now comes this circular, with open encouragement for the racketeers, and a threat for the good G.P. obstetrician. Hands off! We are not to pretend that we are in charge of our patients. We are the least essential members of a team.

I shall continue to tell my patients that the maternity scheme entitles them to engage me for their confinements if they wish. Being engaged, I *shall* "accept full responsibility for the antenatal care, the labour, and the lying-in period." If I am thrown out of the maternity service for this I shall be delighted.—I am, etc.,

Cambridge. H. R. YOUNGMAN.

*** The Secretary of the Association writes: The General Medical Services Committee has dissociated itself from the contents of this circular and has asked the Ministry of Health to receive a deputation on the subject.

POINTS FROM LETTERS

Income Reduced

Dr. R. H. A. RITCHIE (Sutton, Surrey) writes: After the first year of N.H.S. I am one of a large majority of G.P.s whose income has been substantially reduced as a result of the scheme. None of us can continue long under these conditions. What is the B.M.A. doing about this state of affairs? It is galling to find that dentists are in clover. And who are of the greater value to the community, G P.s or dentists?

Allowance for Telephone Calls

Dr. THOMAS LEVEN (Irvine, Ayrshire) writes: Since the introduction of the National Health Service most hospitals have found it necessary to introduce an appointments system, which places upon the general practitioner the necessity of telephoning hospitals to make such appointments for patients who require examination by consultants or specialists. In the case of country and other practitioners who are some distance from suitable hospitals this duty involves considerable expense, which in my view is not adequately covered by the capitation fee. I request that the British Medical Association urge—nay, demand—that the Minister of Health and the Department of Health for Scotland accept the financial responsibilities of such calls, either by allowing their hospitals to accept reversed charges for legitimate calls or by an allowance for telephone calls to all practitioners on the same principle as the Mileage Fund. . . .

Universal Health Service

Dr. JOHN DEBARY (London, E.5) writes: A patient called to see me to-day with the following story. She was staying in Nice, and had a fall on the beach, as a result of which she hurt her varicose leg. She called a French doctor, who applied a dressing and a crêpe bandage. His bill was 23s. She asked me if there was any means of obtaining a refund of this fee from the N.H.S. Whatever next?

Correction.—The Medical Practices Committee states that in the amended Schedule 2 of its Survey of General Practice (*Supplement*, Aug. 20, p. 93) Mildenwall should be spelt as here, and not Mildenhall.

H.M. Forces Appointments

ROYAL NAVY

ROYAL NAVAL VOLUNTEER RESERVE

Surgeon Lieutenant G. R. Kershaw to be Surgeon Lieutenant-Commander.

Temporary Acting Surgeon Lieutenant-Commander A. J. Ward has been transferred to List I of the Permanent R.N.V.R., in the rank of Surgeon Lieutenant.

ARMY

Colonel W. D. Anderton, M.C., late R.A.M.C., has retired on retired pay, and has been granted the honorary rank of Brigadier.

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel J. M. MacKenzie, C.B.E., M.C., has retired on retired pay, and has been granted the honorary rank of Brigadier.

Lieutenant-Colonel J. F. Shepherd, M.B.E., I.M.S., retired, Retired and Re-employed, has ceased to be re-employed in the rank of Colonel as a Consultant, reverted to retired pay, and has been granted the honorary rank of Colonel

Lieutenant-Colonel R. D. Davy, O.B.E., M.C., has retired on retired pay and has been granted the honorary rank of Colonel.

Majors W. F. Hooton, R. M. Henderson, and J. C. Scott, from Short Service (Specialist) Commissions, to be Majors.

Major J. Walsh has retired on retired pay on account of disability. (Substituted for the notification in a *Supplement* to the *London Gazette* dated June 14.)

Short Service Commission, Specialist.—Major R. T. Fletcher, M.B.E., has r

Temporary M.C., has relinquished his commissio

REGULAR ARMY RESERVE OF OFFICERS

Colonel H. C. D. Rankin, C.I.E., O.B.E., late R.A.M.C., having exceeded the age limit for liability to recall, has ceased to belong to the R.A.R.O., and has been granted the honorary rank of Major-General.

Colonel E. P. Allman-Smith, O.B.E., M.C., late R.A.M.C., having exceeded the age limit for liability to recall, has ceased to belong to the R.A.R.O.

ROYAL ARMY MEDICAL CORPS

Major R. W. Chapman, having exceeded the age limit for liability to recall, has ceased to belong to the R.A.R.O., and has been granted the honorary rank of Lieutenant-Colonel.

Major S. P. Wilson, T.D., having exceeded the age limit for liability to recall, has ceased to belong to the Reserve of Officers.

Captain (Honorary Major) C. G. Harper, having exceeded the age limit for liability to recall, has ceased to belong to the Reserve of Officers.

Captain and Brevet Major J. S. Sloper, O.B.E., having exceeded the age limit for liability to recall, has ceased to belong to the R.A.R.O., and has been granted the honorary rank of Colonel.

Captains and Brevet Majors R. C. Aitchison, F. H. Woods, G. H. Wood, E. J. Mannix, M. McGee Russell, H. J. Davidson, M.C., and C. W. Sparks, M.C., having exceeded the age limit for liability to recall, have ceased to belong to the R.A.R.O., and have been granted the honorary rank of Major.

Captains and Brevet Majors J. W. Cannon, A. G. P. Hardwick, M.C., H. Mitchell, and G. Fleming, having exceeded the age limit for liability to recall, have ceased to belong to the R.A.R.O.

Captain H. L. G. Hughes, C.B.E., D.S.O., M.C., having exceeded the age limit for liability to recall, has ceased to belong to the R.A.R.O., and has been granted the honorary rank of Brigadier.

Captain T. E. Osmond, having exceeded the age limit for liability to recall, has ceased to belong to the R.A.R.O., and has been granted the honorary rank of Colonel.

Captains C. J. O'Reilly, D.S.O., W. D. Whamond, A. G. Henderson, and G. Marshall, having exceeded the age limit for liability to recall, have ceased to belong to the R.A.R.O., and have been granted the honorary rank of Lieutenant-Colonel.

Captains G. D. Robertson, R. J. S. McDowall, H. A. Crouch, O.B.E., M.C., I. Aubrey, M.B.E., M.C., D. A. D. Kennedy, M.C., and P. Reid, having exceeded the age limit for liability to recall, have ceased to belong to the R.A.R.O., and have been granted the honorary rank of Major.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Major (Temporary Lieutenant-Colonel) A. G. Henderson, Reserve of Officers, has relinquished his T.A. Commission.

Captain R. F. Guymer, from T.A.R.O. to be Major, and has been granted the acting rank of Colonel.

Major S. P. Wilson, T.D., has relinquished his commission.

Captain C. J. Wells, M.B.E., to be Major.

TERRITORIAL ARMY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

Major (Acting Lieutenant-Colonel) J. B. Forsyth, T.D., from Active List, to be Major, relinquishing the acting rank of Lieutenant-Colonel, and has been granted the honorary rank of Colonel.

Majors T. F. Lalor and A. W. Forrest, from Active List, to be Majors.

Captain (acting Major) I. C. Campbell, from Active List, to be Captain, relinquishing the acting rank of Major.

ROYAL AIR FORCE

Group Captain L. C. Palmer-Jones has retired at his own request.

Group Captain R. W. White has retired on account of medical unfitness for Air Force service.

Wing Commander P. J. McNally to be Group Captain.

Squadron Leaders J. F. McGovern, L. S. Everett, E. W. R. Fairley, and H. O'B. Howat to be Wing Commanders.

Flight Lieutenant S. C. Farman has been transferred to the Reserve, class D, retaining the rank of Squadron Leader.

To be Squadron Leaders: A. L. Knipe, H. O'B. Howat, and L. V. McNabb.

Flight Lieutenants D. S. Grant, W. O. Davies, and J. M. Ferguson to be Squadron Leaders.

Flying Officer P. H. Moore to be Squadron Leader.

ROYAL AIR FORCE VOLUNTEER RESERVE

Squadron Leader C. H. Levick has relinquished his commission on appointment to the reconstituted R.A.F.V.R., retaining the rank of Wing Commander.

Squadron Leaders J. A. Chalmers and P. R. Kemp have relinquished their commissions on appointment to the reconstituted R.A.A.F., retaining their rank.

Flight Lieutenant G. O. Horne has relinquished his commission on appointment to the reconstituted R.A.A.F., retaining the rank of Squadron Leader.

Flight Lieutenants D. St. C. L. Henderson and H. E. W. . . . their commissions on appointment to . . . retaining the rank of Squadron Leader.

Flight Lieutenant W. Lyons has relinquished his commission, retaining the rank of Squadron Leader.

WOMEN'S FORCES

EMPLOYED WITH THE MEDICAL BRANCH OF THE R.A.F.

Flight Lieutenant A. M. O'Riordan has relinquished her commission, retaining the rank of Squadron Leader.

INDIAN MEDICAL SERVICE

Colonel J. G. McCann has retired.

Lieutenant-Colonels W. H. Crichton, C.I.E., A. H. Barzilay, R. I. Reid, F. C. Jackson, W. P. Lappin, O.B.E., and M. K. Bryce have retired and have been granted the honorary rank of Colonel.

Lieutenant-Colonels K. S. Fitch, O.B.E., J. O'Neill, D. McCarthy, R. J. Jarvie, W. Scott, W. T. Taylor, O.B.E., and M. M. Mansfield have retired.

Major (War Substantive Lieutenant-Colonel) J. L. Mewton, O.B.E., has retired, and has been granted the honorary rank of Colonel.

Majors R. D. D. Birdwood, M.C., G. S. Michelson, P. W. Kent, L. H. Cooper, R. M. McCullough, J. L. M. Whitbread, F. W. Sneddon, O.B.E., S. H. Heard, M.B.E., W. S. Hacon, H. F. T. MacFetridge, D.S.O., H. C. Rogers, J. F. A. Forster, M.B.E., E. L. Wilson, J. P. O'Riordan, D. F. Eastcott, and J. M. M. Drew have retired and have been granted the honorary rank of Lieutenant-Colonel.

Majors W. D. P. Griggs, J. J. Woodward, M.B.E., P. M. Kirkwood, M.B.E., and H. V. Morris have retired.

Major R. O. Yerbury has relinquished his commission on appointment to a permanent commission in the R.A.F.

COLONIAL MEDICAL SERVICE

The following appointments have been announced: P. H. Canham, M.B., Lady Medical Officer, Gold Coast; J. A. Gemmell, M.B., Lady Medical Officer, Aden; F. R. MacNaughton, M.B., Medical Officer, Nyasaland; G. Skinner, M.R.C.S., D.T.M., and K. J. Covell, M.B., Medical Officers, Tanganyika; H. S. Bannerman, M.B., Medical Officer (African) Gold Coast; W. S. Kulesza, M.B., Medical Officer, St. Vincent; W. Wolyncewicz, M.B., District Medical Officer, Grenada; P. G. Currid, M.B., D.P.H., Administrative Medical Officer, Superscale Grade A, Federation of Malaya; W. C. B. Harrison, L.R.C.S.I., D.P.H., Senior Medical Officer, Northern Rhodesia; N. E. W. Anderson, M.B., D.P.H., D.T.M.&H., G. M. M. Menzies, M.B., and F. L. G. Selby, F.R.C.S., Assistant Directors of Medical Services, Nigeria; G. I. H. Braine, M.B., D.T.M.&H., and J. E. McMahon, M.B., D.T.M.&H., Administrative Medical Officers, Superscale Grade B, Federation of Malaya; L. F. Chan, M.B., D.T.M., Medical Officer, Grade A, Trinidad; D. H. Vollet, M.B., Ch.B., Director of Medical Services, Basutoland.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

B.M.A. LIBRARY

The following books have been added to the Library:

Adler, A.: Guiding Human Misfits. Second edition. 1948.
Advances in Genetics: Vol. 1—1947 and Vol. 2—1948.
Allen, A. C.: Atlas of Medical Diseases of the Kidney. 1947.
Anderson, D. G., and Keefer, C. S.: Therapeutic Value of Penicillin: A Study of 10,000 Cases. 1948.
Anomaly: The Invert and His Social Adjustment. Second edition. 1948.

Association Notices

TUBERCULOSIS AND DISEASES OF THE CHEST GROUP

The inaugural meeting of the Tuberculosis and Diseases of the Chest Group of the Association, whose formation was approved by the Council on June 27, 1949, will be held at B.M.A. House on Friday, Sept. 23, 1949, at 2 p.m.

All those interested in this new group are invited to attend. Application forms for membership of the group may be obtained from the Secretary, B.M.A. House, or will be available at the meeting.

AREAS OF HOLLAND AND LINCOLN DIVISIONS

The Council has transferred the following areas from the Lincoln Division to the Holland Division:

Urban District of Skegness.

That part of the R.D. of Spilsby comprising the Civil Parishes of Wainfleet All Saints, Friskney, Stickney, Croft, New Leake, Eastville.

CHARLES HILL,
Secretary.

PRIZES FOR MEDICAL STUDENTS, 1950

The Council of the British Medical Association is prepared to consider the award in 1950 of prizes to medical students for essays submitted in open competition.

The subject of the essays shall be "Clinical Teaching in Relation to the Practice of Medicine."

The purpose of these prizes is the promotion of systematic observation among medical students. In awarding the prizes due regard will be given to evidence of personal observation. No study or essay that has previously appeared in the medical press or elsewhere will be considered eligible for a prize. Any medical student who is a registered member of a medical school in Great Britain or Northern Ireland at the time of submission of the essay is eligible to compete for a prize.

If any question arises in reference as to the eligibility of a candidate or the admissibility of his or her essay, the decision of the Council of the British Medical Association shall be final. In determining the number and the value of the prizes to be awarded the Council will take into consideration the number of essays received. Should the Council decide that no essay entered is of sufficient merit, no awards will be made.

Each essay must be typewritten or legibly written in the English language, on one side of the paper only, must be unsigned, and must be accompanied by a form of application which can be obtained from the undersigned. Essays must be forwarded so as to reach the Secretary of the British Medical Association not later than Dec. 31, 1949. Inquiries relative to the prizes should be addressed to the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

CHARLES HILL,
Secretary.

NATHANIEL BISHOP HARMAN PRIZE

The Council of the British Medical Association is prepared to consider the award of the Nathaniel Bishop Harman Prize in the year 1950. The value of the prize is approximately £100. The purpose of the prize is the promotion of systematic observation and research among consultant members of the staffs of hospitals who are not attached to recognized medical schools. It will be awarded for the best essay submitted in open competition. The work submitted must include personal observations and experiences collected by the candidate in the course of his practice. A high order of excellence will be required. No study or essay that has been previously published in the medical press or elsewhere will be considered eligible for the prize.

Any registered medical practitioner who is a consultant member of the staff or senior hospital medical officer of a hospital in Great Britain or N. Ireland and is not attached to a recognized medical school is eligible to compete. If any question arises in reference to the eligibility of a candidate or the admissibility of his essay the decision of the Council shall be final.

Should the Council of the Association decide that no essay submitted is of sufficient merit, the prize will not be awarded in 1950 but will be offered again the year next following this decision, and in this event the money value of the prize on the occasion in question shall be such proportion of the accumulated income as the Council shall determine.

The writer of the prize-winning essay may be required to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate Section of the Annual Meeting of the Association. Each essay must be typewritten or printed in the English language, and must be distinguished by a title and a motto. The essay must not bear the name of the writer, which should be sent with the essay in a sealed envelope bearing only the motto on the outside.

The title of the proposed essay and the motto should also be notified in writing to the Secretary by Dec. 1, 1949, on a form to be obtained from the Secretary. Essays must be forwarded to reach the Secretary, British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1, not later than March 31, 1950. The prize will be awarded at the Annual Meeting of the Association to be held in 1950. Inquiries relative to the prize should be addressed to the Secretary.

Diary of Central Meetings

AUGUST

31	Wed.	General Medical Services Committee, 11 a.m.

SEPTEMBER

9	Fri.	Joint Committee on Fees for Part-time Work under Local Authorities, 2 p.m.
13	Tues.	Proprietary Medicines Committee, 11 a.m.
14	Wed.	Rural Practitioners' Subcommittee 11 a.m.
15	Thurs.	General Medical Services Committee, 11 a.m.
16	Fri.	Committee on Psychiatry and the Law, 2 p.m.

OCTOBER

5	Wed.	Joint Committee of British Medical Association and National Veterinary Medical Association, 2.30 p.m.

Meetings of Branches and Divisions

SOUTH-EASTERN COUNTIES DIVISION

A meeting of the Division was held at St. Boswells on July 3. After Dr. Glover had given a report of the Association's Annual Meeting at Harrogate, the meeting discussed the constitution of the local medical committee. It was decided that the committee should consist of five members from Roxburghshire, five from Berwickshire, five from Selkirkshire, two medical superintendents from Peel and Dingleton, and the medical officer of health of each of the three counties. Seven members should constitute a quorum. Any practitioner could be co-opted for special reasons. The committee should issue an annual report. Dr. Glover proposed that the old committee be re-elected, and the motion was carried.

SUFFOLK BRANCH

The Annual Meeting of the Suffolk Branch was held at Bury St. Edmunds on July 14, with the president, Mr. F. R. Stansfield, in the chair and 33 members present.

The report for the year 1948–9 was unanimously approved. The meeting also approved the establishment of a contingency fund in place of the local levy fund referred to in the report. A vote of thanks to Dr. R. A. Leader, who had audited the Branch accounts, was passed. Mr. Stansfield, the retiring President, then formally introduced Mr. D. J. P. O'Meara as president for the year 1949–50.

The new president took the chair, and was invested with the chain of office. Mr. G. F. Langley, who had been elected by the Branch Council to continue as honorary secretary and treasurer, was then invested with the secretary's badge of office. Dr. R. A. Leader and Dr. H. Roger were elected as public health representatives to serve on the Branch Council.

Mr. O'Meara then introduced Mr. M. W. Bulman, who gave an address on "The New Look in Obstetrics." He said that fear was often responsible for pain in labour in the absence of gross physical defect, and that labour could be postponed by psychological reactions, so that postmaturity, inertia, and delay in the first stage of labour often resulted from the subconscious desire to postpone the feared events. Shock without severe haemorrhage might be initiated by fear.

Lactation had recently been investigated by Peterson in cows, and he had found that peaceful surroundings, one attendant, and a regular milking routine, with milking more frequently than twice daily, benefited the cow and increased the quantity of milk. Applying this to infant feeding, Mr. Bulman suggested that sometimes it was desirable to allow the fractious child to feed more frequently than at the customary three- or four-hourly intervals. The mother and child should be a "biological unit," which would eventually settle down to a routine beneficial to both.

REFORM IN MEDICAL EDUCATION*

BY

W. MELVILLE ARNOTT, M.D., B.Sc., F.R.C.P.Ed., M.R.C.P.

William Withering Professor of Medicine, University of Birmingham

The last quarter-century has seen three notable publications concerned with this subject. First, the excellent report of Dr. Abraham Flexner (1925) on his comparative study of medical education in Europe and America undertaken under the auspices of the Division of Medical Education of the Rockefeller Foundation; secondly, the Report of the Interdepartmental Committee on Medical Schools (1944), under the chairmanship of Sir William Goodenough; and last, but by no means least, *The Training of a Doctor*, by Sir Henry Cohen and his colleagues of the Special Committee of the British Medical Association (1948).

A brief consideration leads inevitably to the conclusion that education in medicine has developed more according to the dictates of expediency and tradition than as the result of integrative development based on continuity of principle. I shall therefore attempt to outline certain appropriate principles and objectives, beginning with the assertion that medicine is essentially a science in that it deals with phenomena and is based on observation, experiment, and deduction, and is an art only in so far as the term means human skill, both definitions being derived from the *Concise Oxford Dictionary*. Popular perversion of these terms imputes to them the qualities of opposites, science being regarded as meaning preoccupation with essentially laboratory aspects of disease, while the latter has come to imply mystic qualities of insight which transcend logic and defy definition.

Enlightened promotion of health and care of the sick must be based on scientific method which compels thorough observation, leading to recognition of causal factors and to interference in natural processes only when there is good evidence that such interference is likely to diminish the disrupting effect of disease on the community or the individual. The clinician who makes his diagnosis from the patient's history and the presence or absence of physical abnormality and applies treatment which favourably alters the disease is practising the scientific method just as much as the experimental biologist who observes the behaviour of a cell in tissue culture, deduces a particular force determining that behaviour, and tests his hypothesis by observing the effect of calculated interference. It makes no difference to the quality of the science if in a particular case the clinician can carry out this process with his unaided senses while in another case he has to extend his sensory appreciation by microscopy, radiography, or chemical analysis. Science is just as much disgraced by the overzealous application of elaborate technical investigation regardless of the patient's emotional state as it is by indiscriminate blunderbuss therapy with a superficial diagnosis or perhaps no diagnosis at all.

The Scientific Method in Medicine

Despite the fact that scientific method was appreciated by Hippocrates and Galen, its substantial application to medical practice is a comparatively modern development; indeed, it is probably incorrect to assume that it is at all widespread even to-day. The reasons for this are to be found, first, in the developmental history of medicine in its relation to mankind, and, secondly, in the prevailing emotional pattern of man himself. Fear is one of the dominant human emotions, and bodily and mental disorder is a potent source of fear both to the sufferer and to his dependants largely because ill-health is a constant reminder of insecurity and mortality. When confronted with illness and the threat of illness the sufferer casts around for help, and the more omniscience and omnipotence he imputes to his helper the greater surcease does he gain from fear.

In the early river-valley civilizations of Babylonia and Egypt medicine was practised by the priesthood, who, greedy for power, relied mainly on mysticism and empiricism for their influence. Throughout the ages the practice of Medicine has been a compound of superstition, empiricism, and scientific method; the last in but small proportion. It is still very true that in order to give patients comfort from their fears it is often necessary for the physician to pretend to a degree of insight and confidence he sadly lacks. Small wonder is it that in these circumstances the systematic practice of scientific method tends to languish. It is but a small step from the physician deceiving the patient to deceiving himself. It is only by thorough grounding in scientific method that the medical practitioner can hope to retain a foundation of intellectual honesty in the shifting sands of emotional prejudice.

The attitude of the public to medicine is, of course, not fixed; indeed, it is changing with astonishing rapidity. One is frequently delighted to find how much intelligent insight laymen have in medical matters. People are beginning to distrust the doctor who goes on treating them for chest disease without an *x*-ray examination, who doses them for anaemia without a blood test, or who tells them

*From an address delivered to the East Yorkshire Branch of the B.M.A. on March 9, 1949.

that their febrile attack is a "touch of malaria" without finding parasites. An increasing number of patients are beginning to suspect that the vast majority of illnesses recover spontaneously and not as the result of the "doctor's medicine." Patients not infrequently come to the doctor saying that no doubt their complaint will right itself, but they would like to know how long it will last and whether anything will hasten recovery.

If scientific method be the most desirable quality in medical practice its inculcation should be the chief endeavour of medical education. The first and main step in its application is the collection and evaluation of evidence directed towards establishing the best possible diagnosis—that is, a diagnosis based on aetiology. In the case of an infective disease this implies the recognition of the causal organism, its source, the mode of infection, and an assessment of factors, intrinsic and extrinsic, which have determined the susceptibility of the patient to attack. In many diseases one has, in the present state of knowledge, to be content with an inferior brand of diagnosis which goes no further than recognizing the probable type of the disease on the basis of similarity to some general qualitative concept. For instance, the diagnosis of effort syndrome is based on an aggregate of disturbances not due to any clearly defined organic or psychological defect in a person whose personality is of the type generally known to be liable to such reactions. The recognition of such inferiority of diagnosis is a constant reminder of the limited horizon, and should act as a spur to the enlargement of knowledge. Scientific method is critical of the quality of evidence and tries always to measure. A complaint of pain is not regarded as of much value until it has been defined in terms of its severity, location, duration, and quality. The statement that tubercle bacilli are not present in the sputum is regarded as of little value without knowing how often the examination has been performed and whether concentration methods have been used and cultures made. A common example of neglect of scientific method is the tendency to embark on a range of laboratory tests without a thorough history. The most important step in the elucidation of an obscure disorder may be the obtaining from another hospital of a report of some antecedent illness or operation.

The scientific study of disease recognizes no limitation of methods of observation. The pencil and notebook can be as effective an instrument of investigation as the electron microscope—indeed, often more so. The only purpose in employing the inferior clinical methods of physical examination of the chest when a radiograph is available is to keep in practice these methods against the time when radiology is not available. It is just as important to appreciate the limitations of a method as to know its possibilities. The good physician appreciates that he deals in probabilities and not certainties. There is no such thing as the "cast-iron" diagnosis. It is a commonplace in medicine to see individuals, condemned to death on the basis of a well-supported diagnosis of fatal disease, gain a reprieve either because of the remote chance of error or the rare regression of the process.

Faults of Educational Practice

An important characteristic of scientific method is that it strives always to be quantitative. The transition from the qualitative to the quantitative marks the adolescence of a branch of science, and the conviction that if a phenomenon exists it can be measured is a sign of scientific sophistication. It is one of the serious faults of current educational practice that it allows people to obtain the hallmarks of higher education without any training in size language. Much effort is expended in developing facility in two or more descriptive languages, living or dead, in history, in formal mathematics, etc., to the complete neglect of training in elementary statistical methods. In my opinion some appreciation of how to assess significance in numerical data, the normal distribution, and the theory of probability is just as important in the educated person—particularly if he aims at being a useful physician—as being able to preserve the integrity of his infinitives and the purity of his tenses. Mathematics to a higher standard, including elementary statistical methods and an introduction to the calculus—most important in biological science because of its preoccupation with rates of change—should be an essential requirement for admission to a medical school. In exchange for this educational benefit I would willingly give the dead tongues, solid geometry, and much else besides.

Another characteristic of scientific procedure is a keen appreciation of the limitations of knowledge. It has been said, whimsically, that one of the functions of a university is to teach what is not known, partly in order to throw into greater prominence the little that is known and partly to stimulate inquiry so as to reduce, however slightly, the seemingly infinite content of the unknown. Progress in medicine has often been retarded by established authority. There is in human nature a deep-rooted fear of the unknown which tends constantly to seek solace in belief in the authority of the elder and to look for inspiration to the didactic rather than the appeal to reason. What in the light of present knowledge looks logical is likely to be quite absurd in the light of future discovery; expressed epigrammatically, the dogma of to-day is the doubt of to-morrow. It was Willard J. Stone (1936) who, in his monograph on Bright's disease, headed a chapter on classification with this apt quotation from Bacon: "The first distemper of learning is when men study words and not matter." It should be the constant endeavour of the teacher in any branch of knowledge—and the principles of science are applicable to all knowledge—to be constantly on the watch to prevent the student believing rather than comprehending. It is the inevitable fate of the teacher endowed with superior intelligence, wide knowledge, and an attractive personality that his followers tend to accept his pronouncements because they are his and not because they represent reasonable deduction from inevitably meagre data. The intellectual vigour and scientific quality of a medical school can be gauged by the quality of the teacher-pupil relationship. An outstanding flaw in this respect is any element of the pompous or pontifical; a sign of grace is an atmosphere in which no student is ever afraid to question or to express doubt and in so doing is assured of kindly and appreciative consideration.

Much misconception has arisen with regard to that curious attribute which is called "clinical instinct," the possession of which confers the power to arrive at a correct diagnosis, more or less, at a glance. By many it is regarded almost with awe as evidence that its owner has capabilities which transcend scientific procedure—something akin to second sight. "He took one look at the patient and said he's a case of acute Hodgkin's"—how often have we heard that sort of story? Such a *tour de force* is a compound of acute observation, extensive experience, and rapid deduction—all perfectly proper—coupled with a large slice of luck. If a clinical teacher indulges in such a diagnostic gymnastic he should take great pains to analyse the processes by which he arrives at the conclusion and

to emphasize that it is no substitute for thorough verification.

Another much more mischievous slur that is often cast on scientific method in clinical practice is the implication that it is in some way antagonistic to the humanity which should characterize the physician in his attitude to suffering. In that the object of the scientific approach is to influence favourably the state of the patient, any lack of sympathy or neglect of the patient's emotional state is just as much a crime against science as it is against humanity.

The distinction between scientific method and empiricism, although very important, is rather subtle, in that the relationship is rather that of the part to the whole. While the scientist is always endeavouring to verify and to extend knowledge the empiric recognizes no such responsibility, but is perfectly content to work within the bounds of current belief. I fully recognize that for those but moderately endowed with intellectual ability a sort of conditioned empiricism is the only possible *modus operandi*, but this should always be recognized as an inferior substitute.

Selection of Teachers

It is clear that no educational system, however perfectly it be designed, can produce good results if it be applied to indifferent students by dull teachers. It is appropriate, therefore, to consider next the selection of the teachers and the taught.

In the past the system of training and selection of the academic staffs of the non-clinical departments of medical schools has been on a very much more satisfactory footing than in the clinical departments. The main reason for this is the circumstance that these men have been "whole-time" university or medical school teachers and have therefore been free to move from school to school, thereby acquiring a valuable breadth of outlook and experience. Furthermore, their advancement has depended very much more on their status in the national or international association of their colleagues than on their local status among those most of whom are unable to assess them as critically as their peers. For instance, the career of a physiologist depends primarily on the opinion that other physiologists hold of him. In my opinion that is the biggest single factor which has promoted the undoubted scientific ascendancy of the so-called laboratory sciences over the clinical departments. In my own alma mater this point is well illustrated in a non-clinical department which in virtue of its whole-time status has been able to maintain in its direction an unbroken dynasty of illustrious scientists.

Promotion to academic posts in the clinical subjects has been handicapped by the fact that until the comparatively recent introduction of whole-time units the field of those eligible has been almost entirely limited to those who had already sunk economic roots in the locality. This has resulted in a great variation of standards and quality from place to place and from time to time in the same place. It is not so much that those responsible have frequently made errors in selection as that sometimes they could have done much better if the field of candidates had been nation-wide instead of parish-wide. The other side of this picture is that many individuals of the highest ability and promise must have been denied opportunity because they had the misfortune to be contemporary with a surplus of quality in their own school and the system denied them the chance to move elsewhere. Previously academic clinical appointments, with the exception of a few whole-time posts, had to be filled from "local talent," and the almost invariable practice was for recognition as clinical teachers to be accorded to those who had been elected to the staff of the teaching hospital, in many places without prior reference to the University, which therefore had little if any direct influence on the appointment.

The position is very much better under the new Act. The substantial payment now given to all clinical staffs should make it easy for a specialist to accept an appointment away from his own school. Whereas previously his survival in a new milieu was dependent upon his gaining in a short time a consulting practice or upon the possession of private means, he now, even on a part-time basis, has enough to keep him going until additional connexions are established.

This severance of geographical economic bonds can confidently be expected to have a great vitalizing effect on the teaching of clinical subjects. It has been clear that many medical schools were decadent from inbreeding. The extent to which this had gone was shown by the fact that, far from deploring and seeking to circumvent the economic factors which limited their choice of recruits to their own school, they had come to invest this practice with a peculiar intrinsic merit of its own, or, as Chaucer expressed it, "to maken vertue of necessite." It seems likely that in the New Order there will be little if any difference in standards of remuneration between academic centres; this circumstance, coupled with migratory facilities, will mean that a medical school will have to compete for its staff, using for inducement opportunity for research, adequacy of clinical opportunity, a restricted quota of general administrative duties, and, above all, an atmosphere charged with a love of learning, a search for truth, and a tradition of discovery. A free migration of staff was probably one of the main factors contributing to the great efflorescence of scientific medicine which occurred in Germany from about 1850 to the first world war.

Let us try to analyse the qualities which should characterize the medical teacher and, in particular, the clinical teacher. The most fundamental attribute must be a thorough training in the method of science. It is this, and this alone, which will mean that his efforts will be characterized by thorough observation, critical evaluation, and intolerance of the specious and meretricious. He should be, or have been, engaged in the active prosecution of research, because the procedure of science cannot be learnt from the grand-stand. It must not be expected, however, that he should always, or indeed often, have been responsible for outstanding advances in knowledge—such achievement comes only to the few. Another quality of equal importance is the possession in outstanding degree of clinical ability with all its implications of experience of humanity in health and sickness, coupled with qualities of compassion and insight without which the successful care of patients is impossible.

Lastly, there is an aggregate of attributes essential in any person whose duties entail human contact and leadership—i.e., the capacity to inspire others, to get the best out of them, and to create an atmosphere of happy endeavour. Although it is hard to put into words, we all know what is meant when it is said of someone that he is "difficult." There are many ways in which this unhappy effect originates, but a common basis of it is intellectual arrogance; contrariwise, one of the most endearing of human traits is humility. However it may come about, it is an unhappy fact that some people possessed of intellectual ability are denied academic advancement solely because of their inability to create happy relations. On the other hand,

outstanding qualities of rapport may more than compensate for shortcomings in other directions, in that they create an environment which enables others to attain a pinnacle of achievement which would otherwise be denied to them.

Selection of Students

Here one enters a highly controversial field. One of the fundamental aspects of this problem is the question whether or not there are enough individuals of sufficient intelligence to meet the demands of the community. The increasing complexity of community organization and the development of technology are steadily shifting the emphasis from brawn to brain, and there is hardly a trade or profession which is not bent on imposing ever higher educational standards on its entrants. Each profession is bent on carving for itself the largest possible slice of the cake of intelligence. This is all very right and proper, but current belief regards the distribution of intelligence in the community as a relatively fixed characteristic susceptible only to slow change over many generations. Intelligence so far as it is understood—and its definition and measurement are relatively rudimentary—is probably not susceptible to any great improvement in any one individual. The *British Medical Journal* in a leading article and in a paper by Smyth (1946), and the similar number of the *Lancet* in 1948, dealt with the subject of selection of medical students. It was made clear that the problem was complex and was fundamentally hampered by ignorance of the qualities necessary for success in medicine. However, a systematic effort is now being made to determine by organized investigation the correlation between various grades of achievement and different combinations of intellectual and personality attributes. It will obviously take years to reach any definite conclusions. In the meantime it is clear that the more effort medical schools take to find out about their applicants the less likely are they to acquire gross misfits. An interview conducted by a small committee is essential. Students who show an outstandingly poor performance during the earlier years of the course should be discouraged from continuing. Britain is no longer wealthy in terms either of man-power or of treasure, and she can no longer afford the luxury of square pegs in round holes.

Integration of the Curriculum

Although my qualifications allow me to speak with any measure of authority only in the department of medicine, I venture to offer some comments on education in the earlier years. Following a good grounding, preferably at the university standard, in physics, chemistry, and biology, the student passes to the study of anatomy and physiology. In this direction the most notable advance of recent years has been made at Birmingham, where under the leadership of Professors Zuckerman, Gilding, and Smout there has been effected a fusion of the normally isolated disciplines of anatomy and physiology. Zuckerman (1947) has pointed out that this separation is a temporary phenomenon which has prevailed for only some 60 years.

In 1845 William Bowman, in conjunction with Robert Todd, produced a great textbook, entitled *The Physiological Anatomy and Physiology of Man*, which made no distinction in its presentation between structure and function. Apparently the separation was in large measure due to the influence of Sharpey, followed by Schaefer, who, while contributing much to knowledge of structure particularly in the histological field, so developed the experimental approach as to establish this tradition as an entity separate from those who concerned themselves more or less exclusively with the direct observation of tissue structure. The same influence led to the curious anomaly that, while macroscopic structure became the domain of the anatomist, microscopical anatomy remained in general within the province of the physiologist. The last two decades have seen anatomists adopting more and more the experimental method so as to restore the former unity of approach. Parallel with this, another and philosophically not dissimilar trend can be discerned in that the physiologist or anatomist—it matters little what you call him—is probing ever deeper into the dynamics of molecular behaviour, making use of the modes of thought and techniques which traditionally have belonged to the chemist and physicist. These developments emphasize that the scientific study of phenomena, particularly biological, knows no narrow traditional boundaries. The approach to a problem may at one time be mainly structural, at another functional. Function may imply the methods of organic chemistry, the techniques of nuclear physics, or the refinements of electrical engineering. The researcher must be a jack-of-all-trades and a master of many, or at least capable of working in fruitful harmony with many masters.

Widening Horizons

The influence of this widening of horizons goes far beyond the most successful fusion of instruction in anatomy and physiology effected at Birmingham. We are now engaged in studying how best to apply this scientific "holism" throughout the whole of the curriculum. The first step in this direction is to make the student's transition from the preclinical to the clinical as smooth as possible and to impress on him that the knowledge and modes of thought he has already acquired form the only secure basis of clinical practice, and that the good clinician shares with the good physiologist devotion to the same scientific procedure. There used to be a time when, the second M.B. hurdle surmounted, the student proceeded to a bookseller to sell his physiology books; he usually retained his anatomy works, because the surgeon has always placed great emphasis on a good knowledge of macroscopic morphology. With few exceptions teachers of medicine and surgery who qualified more than a generation ago have not attempted to base their clinical teaching on physiological knowledge, and therefore the student has not appreciated the concept of a body of knowledge one and indivisible.

This appreciation of the unity of knowledge extends beyond the transition from preclinical to clinical, and we intend to make of it a guiding principle in the reorganization of the curriculum of the clinical years. It is our intention that pathology be the central discipline around which is built the study of medicine and surgery, and at appropriate stages pharmacology and all the other subjects which constitute the traditional more or less independent content of the conventional curriculum.

An essential corollary to pathology occupying the central place in co-ordinated teaching is that it should be one of the subjects of the Final Examination and should be taken within a few months of the examinations in medicine and surgery. It is quite illogical that it should be otherwise, and in this school steps are being taken to effect such an association. It may even be desirable to go further and have written papers and viva-voce examinations conducted jointly by pathologist, pharmacologist, physician, and surgeon. This would serve more than anything else to emphasize to the student the essential unity of these subjects.

The Place of Surgery

In such co-ordinated teaching the place of surgery requires close examination. Traditionally surgery has tended to be taught and practised as a discipline separate from that of medicine. There are obvious though not particularly sound reasons for this dichotomy. The surgeon has in the past had more to offer suffering humanity than the physician, and the rapid development of surgical techniques has in itself been a complex process of immense practical significance. Furthermore the surgeon enjoys a position in public esteem far transcending that of the physician—in some measure due to the inherent drama of the surgical operation and the strong appeal it makes to primitive emotional characteristics. However, in my opinion the time has come for a real *rapprochement* between surgery and medicine. The community of work and interest is far greater than the divergence. The physician need not be a surgeon, but the surgeon must be a physician. They are both engaged primarily in the recognition and study of disease processes, using the same methods of thought and similar diagnostic aids. The difference comes when the surgeon steps into his operating theatre and carries out surgical therapy.

Speaking as a spectator, I would say that the difference between a good surgeon and a bad surgeon is much more often to be found in his ability as a physician than in his purely operative technique. The closest harmony has a beneficial effect on both, particularly on the physician, who comes to appreciate the great opportunities and inevitable limitations of surgery and to realize the utter futility of treating the surgeon as a person whom he directs to do a specific operation. It is essential that the physician call in the surgeon in consultation, not so much to have an operation performed as to get another opinion on the problem in its entirety. In my opinion a very practical method of emphasizing the unity of outlook is to avoid, except for very special purposes, the rigid hospital segregation of medical and surgical cases. I have the inestimable benefit of working with surgical colleagues who permit cases on which they have operated to remain in the medical ward. Witnessing the post-operative course and surgical after-care has an excellent influence on staff and students, and emphasizes that there is no fundamental distinction between diseases treated surgically and those treated medically. I look forward to the day when clerking and dressing as separate disciplines are abolished and students will serve their clinical apprenticeship in hospital units where cases are treated some by surgical methods and some without, and where the surgeon shares with the physician the clinical teaching irrespective of whether operative therapy is applicable.

Lightening the Burden

As regards theoretical teaching in these subjects, close integration will lighten the burden for both teacher and taught. The cry of "Pity the poor student" is often raised these days. It is stated that there is so much more to learn, professors of this specialty and that subject all clamouring for more hours in which to profess their branch of knowledge, with the result that the student is in danger of being utterly overwhelmed by a flood of facts. That this tendency exists I do not deny, but I believe it is due not so much to the acquisition of new knowledge as to failure to discard the old. Viewed rationally, I am convinced that the presentation of a well-balanced curriculum within the compass of the intelligent student—and there is no place in medicine for the dullard—is easier to-day than it has ever been. There are numerous instances of where increasing knowledge has replaced a welter of irrational conjecture by a relatively concise body of knowledge. A very obvious example is drug therapy, in which a small number of potent agents have entirely replaced a wide range of products at best inactive or at worst harmful. Furthermore, the increasing emphasis on scientific procedure with its insistence on the critical evaluation of evidence has made the mere acquisition of facts of less importance. It is futile to attempt to show the student even a majority of the almost infinite varieties of human ailment. The careful study and critical evaluation of a relatively small number of diseases in all their facets constitute a better preparation for medical practice than a motley of fleeting impressions. An essential feature should be emphasis on where to find information rather than on any attempt to overburden the memory.

Clinical teaching to be of real value must be conducted with a small group: it is earnestly to be hoped that the increased number of students will not result in large ward classes. With a small group it is possible to make of each member an active participant in the work of the class. The student is much more likely to carry away a vivid impression of a case which has been demonstrated by a fellow student under the guidance of the teacher than if all the interrogation and demonstration has been done by the physician. We all know the form of teaching in which the lecturer talks the whole of the time, relates the patient's history—or what he thinks ought to be the history—rapidly demonstrates selected physical signs, answers his own questions to his own complete satisfaction, and relegates the students to the role of passive spectators.

Probably as the result of the morbid-anatomical era in medical development with its preoccupation with structure rather than function, there has tended to be undue emphasis placed on physical signs and insufficient attention paid to disordered function as revealed by the history of the illness. Platt (1947) studied the value of the patient's history apart from physical examination as a guide to diagnosis, and came to the conclusion that in 68% of cases an accurate diagnosis—as confirmed subsequently—was made on the basis of the history, while in only 6% was it found either impossible to reach a diagnosis by this means or such diagnosis was completely wrong. This is most important, and cannot be over-emphasized in clinical training. How often one sees clinicians embarking on this or that laboratory investigation or listening intently at a stethoscope or peering into a fundus when all these investigations would have some meaning and coherence if a little time were spent on the history. Much of the trouble lies in the character of the clinical part of final and higher examinations, which places an undue premium on the "physical sign" and makes little if any attempt to assess the candidate's interrogatory ability.

A Welcome Development

A very welcome recent development in clinical teaching has been the enlargement of the scope of social medicine. Previously this subject, or public health as it was called, was more or less limited to State medicine and sanitary science, and was exclusively non-clinical. Although in every group there were notable exceptions, it was on the whole true that conventional clinical medicine concerned itself exclusively with the organic aspects of disease and gave but scant attention to the patient as an individual, the influence of his social environment on the origin, development, and prognosis of his illness, and the effect of this illness on the prosperity and health of the other members of the family. Up till the last few years there was

an excellent reason for this omission in that the contemplation of the social and economic causes and consequences of illness brought inevitable frustration, because the aid and resources necessary to mitigate these influences were either totally absent or were provided by some charity usually gravely hampered by lack of funds. There has grown up under the new social Acts a wide range of assistance which can be brought to the aid of the victims of illness and accident, not as an act of charity but as an expression of the prudence of a community which has elected to insure itself against the malevolence of chance.

Although the general principles and the social biology of social medicine are a matter for a non-clinical department, their application to individual cases of illness is of the very stuff of clinical medicine and constitutes a matter for the clinician. It is in my opinion quite wrong for the physician to limit his view of the case to the details of the disease process and to leave the assessment of the social factors to another person, such as an almoner. The help of the trained social worker is of the greatest possible value, but it achieves its maximum value only in close co-operation with the physician. This emphasis is particularly valuable in teaching, because the general practitioner has rarely got the help of an almoner and he must be quick himself to perceive and alleviate the social stresses of illness.

Conclusion

I can do no better than conclude with a quotation from the evidence that Sir Thomas Lewis presented to the Goodenough Committee; he said of medical teaching that it should "aim at sending the student forth with a well-trained mind, familiar with and critical of sources of information, possessed of a sound knowledge and experience of all common disease, and of disease and manifestation of disease whether common or rare—that is clearly understood. Thus a substantial foundation will be laid upon which, by building as he has been taught, his mind can become well stocked."

In a pamphlet entitled "Hospital Reform in New Zealand" Drs. Selwyn Morris and Douglas Robb advocate a complete survey of hospital resources in the country, with the idea of grouping them ultimately under six regional hospital boards. They say that there are now too many small and unrelated administrative units. The general medical services overlap the hospital work, little attention is given to the care of the aged, and there is an undesirable division of authority between the local hospital boards and the Government department. The regional hospital boards would each serve about 300,000 people, and would have their base hospitals at Auckland, Hamilton, Palmerston North, Wellington, Christchurch, and Dunedin. There should also be an investigation into the nursing services. The existing shortage of nurses has necessitated curtailment of hospital work on more than one occasion.

THE TEACHING OF PHYSIOLOGY

BY

G. W. PICKERING, M.A., M.B., F.R.C.P.

Professor of Medicine, University of London

"The true aim of the teacher must be to impart an appreciation of method and not a knowledge of facts."
KARL PEARSON (1900).

Medical education, said Abraham Flexner, is a problem not of medicine but of education. That statement is as true to-day as when it was made. If we are to judge rightly of what should be sought in teaching physiology we must begin by examining the aims and methods of education and the difficulties of realizing them in the medical course. For one of the major criticisms of medical *education is that the elementary principles of education* have been forgotten.

Education and Instruction

In the older universities a sharp distinction was drawn between education and instruction. The *Oxford English Dictionary* defines "educate" as follows: "To bring up from childhood, so as to form habits, manners, mental and physical aptitudes."

The essence of education is that the student does the work. He is guided and stimulated by his teachers, and his teachers appraise and criticize his efforts. Set classes occupy but a fraction of the student's time-table; most of his time is spent working on his own in the library, the study, or the laboratory. To carry out this system effectively the pupil must have learned how to work and classes must be small, which requires a high teacher/student ratio. The system still operates in sixth-form work in schools and in the older universities, particularly in languages and humanities.

The *Oxford English Dictionary* defines "instruct" as follows: "To furnish with knowledge or information." The teaching is didactic. The student learns by memorizing material which he receives in lectures or from textbooks. His own mental contribution, apart from a feat of memory, is small. This system requires only a small teacher/student ratio. It operates in elementary schools and in trade and technical schools.

The object of education is to train the student's mind, to train it to seek its material from original sources, to manipulate ideas, and to weigh the evidence which bears on these ideas. The well-educated man is not merely a man of superior knowledge; he is also a man of method, a man whose mind is so trained that it can deal adequately with a problem presented to it for the first time. He can clearly define the problem, collect the relevant facts, evaluate what may seem to be contradictory evidence, and arrive at a judgment on the problem. These steps are common to most of the higher intellectual processes that make up the life of a civilized community.

In the case of science the same steps are taken, the facts being first won by simple observation. Then follows a further process which is the most important, and is the peculiar contribution of natural science. This is the method of experiment, which is the essence of the scientific method. Here the observations are made under a variety of conditions, in which one or more variables are controlled, kept constant, or eliminated. It is by the method of experiment that conflicting hypotheses are tested and a decision finally

reached on which, if any, is correct. It is of course chiefly to the scientific method that we owe our knowledge of and ability to control the world of nature, both animate and inanimate.

The object of instruction is to teach a particular system of belief or practice. Thus religious instruction is rightly so called. In the secular field the method is particularly suited to the teaching of an art or a trade or a technique.

Method in Teaching

Since medicine always has been in large part a practical art, instruction clearly has its place as a method of teaching. But when medical schools were incorporated in the universities—and the past two years have witnessed the completion of this process in Great Britain—it was tacitly admitted that the educational method, which is the chief concern of the universities, should play an increasingly important part. A century and a half ago there may have seemed to be little justification for such a step. But the rapid progress in our understanding of biological phenomena since that time has now made the use of the method imperative. For the most important asset that the newly qualified doctor should have is an ability to learn both from his own experience and from that recorded by others.

Now, if we look at the medical course of to-day we find that the method of instruction is almost in sole possession of the field. The educational method is used sparingly or not at all. The result is what would be expected. In the words of the Royal College of Physicians Planning Committee (1944):

"We are agreed that, quite apart from lack of character and ability that may be avoided by improved recruitment and selection, the average medical graduate has defects which are to be attributed chiefly to the manner of his training. He tends to lack curiosity and initiative; his powers of observation are relatively undeveloped; his ability to arrange and interpret facts is poor; he lacks precision in the use of words. In short, his training, however satisfactory it may have been in the technical sense, has been unsatisfactory as an education."

There are three reasons for the failure to use the educational method in medicine. First, historical; the course has grown out of a course of instruction, and the natural tendency is against change. Secondly, the crowding of the curriculum; since the student learns more slowly by his own efforts than by the memorization of predigested information, less ground can be covered in the time. Thirdly, the small size of university staffs.

Of these causes the second is the most difficult to combat. There is a tendency to forget that the unfortunate student has such a thing as a mind that is worth cultivating; there is a tendency for each teacher to regard his own subject as the most important in the whole curriculum, to forget that in medicine there are some 14 other subjects, and ruthlessly to demand his pound of flesh. The first cause needs no discussion; the third is ceasing to be operative since the increase in Government grants to the universities.

It is quite beyond the scope of this article to suggest what should be eliminated from the curriculum. All bodies who have considered the matter agree that much should, but until medicine has an enlightened dictatorship, or until some of us are prepared to be consistently rude to our colleagues, little will be done. It is urgent that it should be done, because the recent increase in university staffs makes the increasing use of the educational method a practical proposition for the first time.

The Place of Physiology

Against this background we may consider the place of physiology, the opportunities it offers as a medium for training the mind, and the way in which these opportunities can best be utilized. No doubt it is chiefly because I am not and never have been on the staff of a university department of physiology, though I have long been a member of the Physiological Society, that the Editor asked me to contribute this article.

Physiology and the closely related biochemistry have made enormous strides in the last century. Much is now known of the behaviour of the mammalian body, both in terms of the body as a whole and in terms of its constituent organs and cells. This knowledge forms an essential basis for understanding the behaviour of the body in disease, and thus is an essential basis for clinical work and its numerous subdivisions. It is therefore quite obvious that during his course of physiology the student should gain as complete as possible a knowledge of the contemporary status of the subject.

The course in physiology, however, has another and even more important function. One constantly hears that the premedical subjects of chemistry, physics, and biology are justified because they teach the student the fundamental principles and methods of science. From my own experience as a recipient, as a donor, and as an observer of the premedical course in more than one university and school, nothing is further from the truth: the course tends to degenerate into a cram-class in which the student learns by rote. Of all the subjects in the medical curriculum proper none is a better vehicle for the teaching of method than physiology. For physiology has been won by the experimental method, and the exponents of this method in physiology have numbered amongst them some of the greatest names in science. It is not enough, therefore, for the teacher in physiology to give his students a comprehensive knowledge of the subject He must also give them a firm foundation in the scientific method, and particularly in the experimental method. For if he does not, he is failing in his most important duty, for no other teacher in the curriculum has similar opportunities for the exposition of method.

By physiology we usually mean animal physiology. While there are many points of resemblance in the behaviour of all animals, there are very numerous differences in detail. The fish differ from amphibia, amphibia from birds, and birds from mammals. Even in the mammalia there are often striking differences between genera and even species. Now it has been maintained that it does not matter which animal is used to illustrate physiological behaviour. This is incorrect. To quote from the Cambridge University Report on University Education and Business (1945):

"Any subject can be used as a means of training and developing the intelligence, and when intelligence has been developed by exercise it will be a better instrument for studying other subjects. This, however, is not the same as saying that the clarity in thought attained in one subject is directly transferable to another. In order to secure clarity the ideas involved must be easily manipulated, and an early acquaintance with these ideas is a great aid to proficiency. Further, if the subject is one for which the student has special interest, he will more readily advance by using his innate ability unchecked by lack of interest in the subject-matter. Perhaps one of the most useful conclusions of experimental psychology has been to stress the importance of developing intelligence in conjunction with special aptitudes and interests."

Since most students of physiology are going to be doctors, and will be primarily concerned with man, it is clear that,

in presenting physiology to the student, man should be used wherever possible; if not man, the mammal. It is easier for the student (and in view of the strain of the curriculum this aspect should always command respect) if human or mammalian physiology is the medium in which he is taught. While this should be a guiding principle, it need not be adhered to slavishly. There are aspects of cellular physiology which can at present be worked out only in invertebrates, and the energetics of muscular contraction are as yet well elucidated only in the frog. There is one other important point. Most active laboratories have a team or teams working on a limited field. It is natural that in the relevant school most attention should be paid to this particular field. From the educational point of view this is the correct course, because the student will learn method best by working in the field which his teacher has mastered.

Techniques of Education

Having defined our objectives, in which method has been stressed, and having discussed the principles guiding content, we may proceed to discuss the techniques of education that are available—the lecture, the tutorial, and the practical class.

The Lecture

When the attitude of a teacher is that of an instructor the lecture becomes a dogmatic exposition which is no more than a substitute for the textbook. It is what my old teachers in Cambridge used to define as a system for transferring material from the notes of the lecturer to those of the student, without the material passing through the minds of either. It is of limited value, but it is popular with the student in these days of overloading, because he feels that if he learns his lecture notes he should be able to pass his examination. To the teacher who regards his function as that of an educator the lecture has a different purpose. No attempt is made to cover the ground completely; certain problems are taken up and defined, and the experimental evidence which has been accumulated in exploring the problem is set forth and critically assessed.

I always remember in this connexion an elementary lecture at Cambridge by Sir Joseph Barcroft on the kidney. He described briefly the kidney structure and told us he was going to ask six questions and describe one experiment to answer each of these questions. The questions were: Does the glomerulus of a frog act as a filter (evidence the constitution of the glomerular filtrate as obtained by Richards by puncturing Bowman's capsule with a micropipette)? Does the tubule of the frog reabsorb? Does the tubule of the frog excrete? The same three questions were asked about the mammal. This lecture was remarkably helpful in having picked [illegible] kidney function, and excellent as an exposition of the scientific method. It was to my mind the model of what a lecture should be.

The Tutorial

The second method is the tutorial. By a tutorial I do not mean the revision class to which we have become accustomed in our medical schools, which is nothing more than a cram-class of the most brazen variety, with examination success as its only goal. Not surprisingly, this kind of class has become popular with the overburdened student, and his teachers can see in it a sign of the mental disease of which they are the chief creators. I mean by a tutorial a class of the kind that is so important a part of the educational method as practised in the sixth form of a good school and at Oxford or Cambridge.

The essence of such a class is that the students prepare a subject by reading a list of references which they may have been given by the teacher. The results of the student's reading and deliberations are presented either as an essay or verbally to the group. The function of the teacher is to criticize and to comment on the matter and form of the presentation. These classes are inevitably small, and they can be effectively conducted only if the teacher realizes their function and has the ability to get to know his students and to help them individually. Outside Oxford and Cambridge this method is not to my knowledge used in Great Britain. Of all the subjects in the medical course none is more suitable than physiology for its employment. Nevertheless it will be difficult to start such a class, for so few of the graduates we turn out of our medical schools understand the principles of education, and fewer have any knowledge of how to apply them. The danger will be of producing just another cram-class, always popular with the student and requiring no mental exertion by the teacher.

The Practical Class

It is in the practical classes that the content of physiology assumes major importance. I am glad to find that the day when the frog was the mainstay of practical physiology is nearly over. Wherever possible man should be used as a subject; if not man, the mammal. Now it is possible to illustrate a remarkable variety of experiments relating to the fundamental principles of physiology by experiments on man. Professor Landis, of Harvard, has instituted such a class, which I saw in operation. Lewis's *Exercises in Human Physiology*, 1945, is a compendium of simple and very illuminating experiments drawn largely from his own field; many experiments of similar type could be found elsewhere to complete the course.

The advantage of such a course is obvious. The student becomes familiar with the workings of the human body and with the approach to human problems through experiments on man himself—an invaluable prelude to medicine. It is one of the major shortcomings of contemporary medicine and surgery that so little use has been made of the experimental method, that we have failed to verify so much that is capable of proof or disproof, and that we accept as fact so much that is no more than a tissue of dreams. The difficulty in arranging such a class is the space required to accommodate so large an experimental animal and his observers. When new departments of physiology are built they should provide for such a laboratory, which could also be used for teaching elementary physical signs.

Classes in mammalian physiology in Great Britain will be difficult to organize so long as they are based on the cat or dog, uncommon and expensive animals the use of which is much hedged round by restrictions. In Adelaide I saw a most successful practical class in which the wild rabbit was used. These animals are apparently very tough and can be trapped cheaply. Of a team of six students, there was one anaesthetist, one surgeon, and one assistant, two in charge of recording apparatus, and one in charge of notes. A series of 12 experiments was done, including the occlusion of the carotids before and after denervating the carotid sinus with collections of blood from the [illegible] prarenal vein.

Sir Stanton Hicks told me that these classes had been remarkably successful. The students learned to work as a team and succeeded in carrying out in a remarkably successful fashion even a very difficult technique such as that just quoted. But one of the great points about such a class is the interest it stimulates. The student is able to

record these very dramatic facts for himself, and Sir Stanton said that one of the major difficulties in running the class was to get the students out of the laboratory in time to have it cleaned up for the next day.

The Student's Problem

Education is essentially a partnership, and having considered the teacher's side we must not forget the student. The student of to-day faces a problem that is in many ways much grimmer than that which faced his predecessors. Often he is dependent on a grant which continues only so long as he passes his examinations. The exigencies of war and the pressure of students on medical schools have led to the practice of expelling a student after one or two failures in an examination. The student's request is accordingly a simple one: he asks to be put through his examinations. Whether or not he is educated in the process is to him a secondary consideration.

If we teachers place a high value on education, and on method, we must ensure that the student who has acquired this is duly rewarded. This can be done in two ways: by taking into account his performance in class during the year, and by ensuring that the examination is largely a test of method. For I doubt whether we are in a position to do away with examinations. Nevertheless, they require the same careful study as the course itself. If the course is being designed to impart method the examinations must be designed to test how far method has been acquired. And since all professional examinations have and must continue to have an external examiner, it is clear that he also must understand and be in sympathy with what has been attempted. His selection therefore requires equal care.

Conclusion

The reader who has persisted thus far may remark that this article is just loose talk, that the writer has not laid down a precise syllabus, that he has not told the physiologist what he must teach and what he need not, and that he has not laid down the number of hours to be devoted to lectures and tutorials and practical classes. I have not done this, for three reasons: first, because I was not competent to do so; secondly, because I profoundly distrust any precise statements on matters that are so controversial; but my chief reason is that these matters are of less importance than the attitude of mind of the teacher and the student. I personally do not mind if a student comes to me in medicine with enormous lacunae in his knowledge: these he can very quickly repair once they are pointed out to him, if he has learned how to learn. But I do very strongly object when I meet students who have already had three years of university education, and who, far from having the scientific attitude of mind, have not the least idea what the scientific method is. That I regard as the most heinous crime of our system of medical education to-day.

"It could be said, I suppose, that of all the changes which have occurred in the last half-century, the most beneficent are the discoveries of medical science. Assuredly much pain has been alleviated and much hope created by contemporary researches into the functioning of the endocrine glands and by such discoveries as insulin and the many varieties of antiseptic and anaesthetic drugs."—Mr. Harold Nicolson, the *Spectator*, August 19, 1949.

THE TEACHING OF CHEMISTRY

BY

E. C. DODDS, M.V.O., M.D., F.R.C.P., F.R.S.

Courtauld Professor of Biochemistry, University of London

The teaching of chemistry to medical students has been one of the most controversial subjects in the whole of medical education. That a sound knowledge of organic and physical chemistry is necessary for the proper understanding of medical and allied subjects will be disputed by nobody; but what is the best method of imparting this knowledge? Medical students are taught chemistry usually in one of two ways. If they are students at a university possessing a single chemistry department, they attend special courses in this department. On the other hand, if they are students at a medical school attached to one of the big London teaching hospitals, the medical school in most instances provides teaching of the complete curriculum and the student is taught chemistry in the chemical department of the medical school.

Two Methods

It must be emphasized at the outset that these instances differ entirely in the problem they present. A university chemical department is naturally a highly specialized and well-equipped institution with a series of professors for organic chemistry, inorganic chemistry, physical chemistry, and so forth. Each of these subdepartments of chemistry is fitted with modern apparatus and well-turned-out teaching laboratories. Here are all the facilities for teaching, together with the necessary inspiration and drive given to a subject by those engaged in original research. Theoretically at least, in these circumstances the medical student should have the advantage of an ideal education in chemistry.

Before considering in detail what happens to him in this department, let us turn to the potentialities for the student in the hospital medical school. From the material point of view he is obviously very much worse off than his fellow-student at a university chemical department; for medical schools cannot afford to maintain and equip a chemical department of the same standing as that in a university. They obviously cannot afford to have three or four professors for the teaching of the various branches of chemistry, nor have they the space for separate departments of inorganic, organic, and physical chemistry. Again, the equipping of laboratories of this type with modern apparatus would be an expense beyond their power. The chemistry department is therefore organized on different lines, consistent with its admittedly more limited scope. One man is responsible for organizing the teaching in all branches of chemistry, and he is assisted by more junior lecturers and demonstrators. The teacher of chemistry in the hospital medical school can claim an advantage over his counterpart in the university chemical department. Having spent years in a medical school, he has become acquainted with the ways and minds of medical students and is therefore perhaps in a better position than others to have responsibility for their chemical instruction. We can quote many examples of distinguished organic chemists who have devoted the greater part of their lives to the teaching of medical students.

To switch back to the university chemical department, one must point out that the position of such a student is not quite so enviable as would appear at first sight. For a number of years past every university chemical department in the country has been grossly overcrowded

with honours and ordinary-degree students taking chemistry in its various branches as their main subject. Laboratory accommodation for practical work in every university in the country is inadequate, and almost without exception practical classes have to be run in shifts. The director of a university chemical department would indeed be abnormal if he did not regard the purely chemical student as his first charge, and not unnaturally the medical students are regarded as an unfortunate burden and necessity. They have to be fitted in to suit the convenience of the degree students, and usually the less senior and inspiring teachers are allotted for their instruction. We can sympathize with the purely chemical teacher in the university chemical department, to whom by definition the medical student must be little other than a nuisance.

Value of Chemistry to the Medical Student

It is very difficult for the medical student to regard the instruction for the first and second medical examinations as other than hurdles and obstacles put in his path to prevent his getting to the clinical work in the hospital. Chemistry to him means a kind of barbed-wire entanglement through which he must cut his way and so get to the patients in the wards. Unless he is very carefully taught, he does not realize that chemistry is being taught him for its intrinsic value, nor how it will help him when he does get to the wards. The teacher in the university chemical department completely loses sight of the medical student as soon as he has passed his second M.B., and one can well understand the lack of interest which must inevitably arise in these teachers.

We are faced, therefore, with an unsatisfactory state of affairs both in the university chemical department and in the hospital medical school. In order to solve this difficult problem we must first of all try to define how much chemical knowledge is necessary for the efficient practice of medicine. This is said advisedly, since we must never lose sight of the fact that the main function of the medical schools is to produce practising doctors and not medical research workers. Every commission and committee that has sat on the revision of the medical curriculum has had ponderous and far-reaching comments to make about the teaching of chemistry, but it is my opinion that very few people who have studied this problem really see it in its proper perspective.

Obviously the ideal form of education would be to give the medical student a competent working knowledge of organic chemistry and biochemistry. To do this would take several years of study of chemistry and later of biochemistry alone. It is obvious that such a course is impossible, and we are therefore faced with the limiting factor of how much knowledge can be imparted to the average student in the six or seven years during which he is available for tuition at the medical school. The amount of time allotted for the teaching of chemistry and biochemistry has been settled as a result of uneasy compromise between the warring factions of anatomy, physiology, and chemistry. The only practical way to regard the problem is to accept with as good a grace as possible this allocation of time and to see what can be fitted into it.

Co-ordination of Work

We may assume that the student of to-day, and certainly of the future, will come to the medical school with a fairly competent knowledge of elementary inorganic and physical chemistry, and either a smattering of organic chemistry or none at all. It would seem to me that the first and most important consideration is that the chemical course for the student should be treated as a whole from the moment he enters the medical school to the time when he is dealing with chemical pathology in his final year. In the past this has certainly not been the case. In the university the chemistry and physical chemistry have been taught in the chemistry department, biochemistry has been taught by another group quite independent of the former, and the chemical pathology has been dealt with by an entirely separate department. Again, in most institutions, little or no attempt has been made to co-ordinate the work of these departments, with the result that a student may be taught to estimate chlorides in the inorganic chemical laboratory in his first year and may be taught an entirely different method of estimating chlorides in biological fluids in his second or third year, and is possibly given an entirely new method in the chemical pathology department. This segregation of the three periods of his chemical education leads to intellectual resentment on the part of the student, so that he almost takes pleasure in forgetting and refusing to apply what he has learned in the previous department.

Few would deny that those responsible for the teaching of the inorganic and physical chemistry should be sufficiently in touch with biology and the biological outlook to impress on the student that when, for example, he is conducting experiments on osmotic pressure in the inorganic chemical laboratory in the medical school or university, which seems to him so remote from the eagerly awaited ward or operating theatre, he is really actively preparing himself for this period. This making the student aware that his chemistry is being taught him for his own ultimate good, and that he should not regard it as a particularly unpleasant obstruction in an obstacle race, must run through the whole of the teaching of chemistry.

This question of the co-ordination of the various branches presents a difficult problem. One way to settle it would be to arrange for all the chemistry taught to the medical student to be under the control of one authority. This experiment is at present on trial at the Middlesex Hospital Medical School, and has now been operating for three years. It is as yet too early to give any judgment on the practical results, as the scheme will obviously have to be in operation for at least six years in order that the final-year students shall have been through the whole of the chemical course. The important point is that accurate co-ordination be obtained. Provided some scheme is put into force which ensures this, the teaching of chemistry to medical students is bound to improve.

Choosing a Syllabus

If this be accepted as the organization, we still have to face the further difficult task of choosing a syllabus. It is obvious that in the limited space at my disposal this important subject can be dealt with only in the most general terms. It would seem to me that the chemical education should be pyramidal in its construction—that is, the base should be extremely broad so that the student is grounded in the basic principles, and that as the teaching advances from inorganic and physical chemistry to organic chemistry the field can be narrowed as the pyramid rises.

Thus it is obviously important that a really sound knowledge of the physical chemistry of solutions, electrolytes, osmotic pressure, and colloid chemistry be given to the student. So far as is possible this should be treated in a non-mathematical manner. Many experts will object to this and say that it is impossible. After many years of teaching medical students, I have been impressed with the

curious allergic objection that they have to any form of mathematics. This curious phenomenon is well known to all teachers, and one of the surest ways of alienating a class of medical students is to introduce some mathematical formula even of the simplest character. If enough trouble is taken by a sympathetic lecturer, this cardinal error can be avoided, and it is possible to explain to students the phenomena of physical and colloid chemistry without recourse to higher mathematics.

In the past one of the great difficulties in designing a course of chemistry for medical students has been the different types of school education. Thirty years ago the teachers in the first year might be faced with a group of students who varied between two extremes. At one end of the scale was the classically educated boy from one of the older public schools who knew no science at all, and at the other end the boy from the secondary school who could have passed his first M.B. in physics and chemistry the day he entered. From that time up to the present this difficulty has gradually become less and less, and to-day every student entering a medical school has at least some knowledge of physics and chemistry, and very often also of botany and zoology. At the present time, with the possibility of the abolition of the matriculation examination and the substitution of the new certificate of education, it is premature and impossible to say what will happen with regard to the preliminary education of the new entries. It is almost certain, however, that in the medical schools we can anticipate receiving students who have an increasing knowledge of the basic scientific subjects of physics, chemistry, and biology.

It is not the function of this article to discuss how much of the old first M.B. work should be done in school; the construction of the chemistry syllabus will therefore be based on the assumption that the student entering a medical school has an elementary general knowledge of inorganic and physical chemistry.

Organic Chemistry

The organic chemistry syllabus has always been one of the biggest bugbears of would-be reformers. The teacher of medical chemistry in a hospital medical school, in order to justify the importance of his subject, will try to make the syllabus as wide as possible, whilst the medical student in the university chemical department is often forced to attend lectures and practical classes on chemical subjects which he knows will never be of any interest to him. It would seem to me that we can profitably narrow this field of organic chemistry and restrict its teaching to those substances which are of importance in the body. These, by and large, will include proteins, fats, carbohydrates, purines, sterols, and pigments, and in order to understand the chemistry of such substances the student must know something of the basic aliphatic and aromatic compounds. This list is formidable enough, as anyone with knowledge would admit. There is obviously no point in teaching the medical student elaborate details of synthetic organic chemistry, nor is there any point in dragging him through a lot of dyestuff chemistry and similar fields so far removed from his own.

One of the most important errors to avoid is the feeling of satisfaction that some teachers and students get through memorizing formulae. This has always been one of the curses of medical chemical education. So many biological examiners experience a feeling of erudition when they can demand the writing of a formula for a steroid hormone from a student. It is most unfortunate that so many medical students, and in fact many of their biological teachers also, feel they understand the whole sterol field because they can draw a cyclo-penteno-phenanthrene formula on the blackboard. What is much more important is that the student should realize that the fusion of a number of saturated six-membered rings gives rise to the possibility of innumerable stereo-isomers in this field, and that it is therefore possible to have a whole series of cortical steroids all with very similar formulae. In addition, the position of polar groups, such as methyl, hydroxyl, and ketonic, can modify the properties to such an extent that it is essential to have an idea of the importance of their positions in relation to configuration.

Practical Teaching

Up to the present I have dealt mainly with the theoretical side of the course in chemistry. Perhaps even greater difficulties are caused by the wide divergence of expert opinion on the question of practical teaching. Teachers can be divided into roughly two classes. There are those who maintain that the student can obtain valuable instruction by his making complicated quantitative estimations, and that even if the results are wide of the mark the fact that he has struggled through the determination will have demonstrated to him the principle of the method. The second group of teachers, to which I very definitely belong, maintain that this performance of elaborate experiments in determination, with the production frequently of ridiculous results, is not only useless but actively dangerous from an intellectual point of view. It encourages the development of the old bogy of the medical student already referred to—namely, that subjects like chemistry, etc., are put there as traps and obstacles to prevent him from getting on. The second group of teachers believe that the student should attempt experiments in quantitative determination only of a complexity that will enable him to practise them well enough to get accurate and reproducible results. The more complicated investigations can be shown in lecture demonstrations.

Many teachers seem to delude themselves into believing that medical students can perform accurate gas analyses with the Haldane apparatus and can do accurate blood analyses. Those of us who have had experience of running biochemical routine laboratories know the length of time it takes to train a technician in one or two blood or urine quantitative determinations. With an intelligent technician it requires weeks of training before one can rely on his results, and it is therefore most unfair to expect a medical student to master the more complicated determinations in the short time at his disposal.

Another important development in the modern teaching of chemistry to medical students is the very wholesome trend of employing biological material, and wherever possible human material, for experimental practical work. It is very obvious that if one can design experiments where the students examine the effect of some reaction on their own blood and urine they take much greater interest than if they are handed out some made-up solutions. The practical course in organic chemistry has been evolved in most schools and universities to contain exercises such as simple synthetic preparations which enable the student to understand the elementary principles of organic synthesis.

In biochemistry the same principle should hold, and the student should only do exercises which he can accomplish efficiently. Wherever possible the more complicated exercises should be illustrated by carefully thought-out lectures and demonstrations.

Chemical Pathology

Finally, turning to chemical pathology, for the general course of practical instruction in examination of blood and urine from different types of cases it has always been found a good plan, if accommodation is available, for students to be able to carry out examinations on patients whom they are looking after in their medical and surgical appointments. While this tends to be a nuisance to those in charge of the laboratories, there can be no doubt that many biochemists of distinction to-day have entered the subject through this portal. In some institutions the students actually perform the routine investigations on the patients. In my experience this puts far too much strain on the students, and the results cannot be relied upon.

If the continuity of teaching is maintained, the student will appreciate it fully when he comes to his chemical pathology. If the scheme outlined has been properly implemented he will fall on the urinary steroidal examination in adrenogenital syndrome almost with relish and will start his studies of diabetes and other metabolic diseases with interest based on sound chemical knowledge. Another advantage of such co-ordination is that it enables the institution to provide interest for the teachers of inorganic and organic chemistry. If they are in the same department as the teachers of biochemistry and chemical pathology they do not lose sight of their students, and then they have the stimulus of research work in that they are in constant touch with biological material. This is very different from the old regime in medical schools where the teacher of inorganic and organic chemistry had no connexion whatsoever with those dealing with biochemistry and chemical pathology, being segregated in a separate department.

Conclusion

Anyone who attempts criticism of the medical curriculum or points out faults in the existing system of teaching exposes himself to a battery of criticism, and this applies doubly to the person who is rash enough to publish his article in a journal permitting correspondence. There is no doubt that many of those who read these brief notes will be tempted to write at once and say that these objections certainly do not apply to their particular university or medical school. I trust that those who are kind enough to study my remarks will understand that they are meant in an entirely general sense, and that there must be institutions where some or possibly all of the defects are avoided or minimized.

The Dutch have long realized the limitations of their own language as a medium for scientific expression. In the 17th century Leeuwenhoek was sending accounts of his discoveries to London for publication in English in the *Philosophical Transactions*, and as recently as 1947 English was chosen as the most suitable language for the series of abstracting journals published in Amsterdam under the title of *Excerpta Medica*. Dutch surgeons have now commenced publication in English of a new journal for their specialty, the *Dutch Archives of Surgery* (*Archivum Chirurgicum Neerlandicum*), which is sponsored by the Dutch College for the Advancement of Surgical Science. By this new journal surgeons in Holland hope to enjoy the advantages of international criticism and a broader interest in their work. Papers will be published in French or German also, but manuscripts submitted in Dutch will be translated into English. The journal will appear quarterly, at an annual subscription of £2 2s. The agents in this country are Messrs. Baillière, Tindall and Cox.

ON THE TEACHING OF BIOLOGY AS A PREPARATION FOR MEDICINE

BY

F. A. E. CREW, M.D., F.R.C.P.Ed., F.R.S.

Professor of Public Health, University of Edinburgh

It is most unlikely that further discussion concerning this particular topic can yield conclusions significantly different from those presented in the 1948 Report of the B.M.A. Medical Curriculum Committee. Nevertheless it is perhaps desirable that such discussion should proceed, since in spite of the appearance of this most admirable report there is still much disputation and not a little misunderstanding both among medical students and among their teachers concerning the contribution which biology makes, or is expected to make, to the education of the future practitioner of medicine.

Aims of the Curriculum

The structure of the curriculum and the place of biology within it cannot be considered profitably until the aims of the curriculum are known. They certainly are not solely the production of the general practitioner, that lowest (or highest) form of professional life, the specialist in some particular branch (or twig) of medicine, or the medical scientist (physicist, chemist, anatomist, physiologist, pathologist, bacteriologist, biochemist, pharmacologist, and the like). There would seem to be a general though occasionally hesitant agreement that the product is meant to be a person who, in virtue of his initial organic endowment and early upbringing and as the result of his exposure to this curriculum, has become fitted to pursue further study and thus ultimately equip himself with that constellation of qualities, personal, social, and professional, that is necessary for the kind of work he proposes to do and for the kind of life he proposes to lead. Graduation is thus the starting-point for a career in one of the three major provinces of medicine. The graduate can proceed thence to become a medical scientist whose hope is to advance knowledge in a particular field of medical science, a specialist in medical practice dealing with some particular part of a human being in relation to the rest of him (for example, an ophthalmologist; a specialist in the utilization of some particular technique demanding a mastery over some particular complicated machinery and of value in diagnosis and therapy—e.g., radiology; a specialist in some particular field of medicine—e.g., public health), or a generalist in medical practice concerning himself with the total individual in relation to his total external physical and social world.

So far as the future practitioner of medicine is concerned, the aim of medical education is to produce out of an individual with the appropriate personality, aptitudes, and inclinations an educated person. He must be fitted to claim his proper place in the society of which he is a co-operative member and be equipped with the special outlook, knowledge, and skills which will enable him to render service of a special and expert kind to the community; this service taking two main forms—the skilful application of his special abilities to the immediate task of conserving, augmenting, and restoring the health, happiness, and efficiency of individuals or of a community, and the expansion of the special corpus of knowledge which is medicine by additions thereto gleaned from his own activities and experience.

Groundings in General Science

To medicine can be given several definitions, every one of them plausible and attractive. But for the purpose of this particular discussion let it be granted that, *in the main*, medicine in action, the practice of medicine, is the application to human and social affairs of medical science (that part of scientific knowledge which has its bearing upon medical theory or its application in medical practice). Medical science is a part of general science but has an added vocational value. It is but reasonable, therefore, that the future practitioner of medicine should receive an adequate introduction to those disciplines which are grouped under the heading of medical science. Since medical science is science, it is equally reasonable that the student should receive an adequate introduction to science itself.

The curriculum as we know it is divided into three interrelated parts: (*a*) an introduction to general science (with special reference to physics, chemistry, zoology, and biology); (*b*) a grounding in the sciences on which the theory and practice of medicine rest (anatomy, physiology, biochemistry, bacteriology, pathology, pharmacology, etc.); and (*c*) an extensive introduction to the theory and practice of medicine (total medicine applied to the affairs of an individual patient, of a series of these, or of a group). Since group (*b*) rests on group (*a*) it can of course be argued, and quite commonly and rightly is so argued, that in the ultimate analysis the sciences on which the theory and practice of medicine are based are physics, chemistry, and biology. However, let this pass. All that this present approach demands is the acceptance of the view that the teaching of medicine is not to be detached from the teaching of science and that the practice of medicine is not to be undertaken by anyone who is unacquainted with science.

There is another reason why an introduction to general science should be included in the medical curriculum. The history of our society is from its beginnings, and especially since the Renaissance, the narrative of science in application, and the possibilities of the continuance and further development of our way of life depend on the even more intensive application of science to its affairs. The practitioner of medicine is a citizen as well as a doctor, and as such should be well informed concerning these matters. Furthermore, it must remain impossible to understand the place which medicine occupies in our society until it is understood in what ways and to what extent science has shaped our social philosophy and has fashioned our social aims, and in what ways and to what extent the prevailing social philosophy and aims have moulded the philosophy of medicine.

The promulgation of the theory of evolution and its general acceptance produced great changes in our concepts of the world, of mankind, and of disease. Man, who had been a puny creature imprisoned in a hostile, narrow, and incomprehensible world, whose heart had been chilled by fear and whose mind had been blinded by superstition, was liberated. His world became a potentially hospitable, friendly, bountiful environment which could be shaped by him to satisfy his every physical need. Man himself became part of organic nature, a product of a continuing evolutionary process. Neither he nor the social institutions which he had invented were final static things. He could hope to gain the knowledge concerning them that, translated into power, would enable him to change them according to his desire. Disease, formerly to the masses the handiwork of demons or the sign of the wrath of an outraged, malevolent, and implacable deity, became the manifestation of a disharmony between man and the other components of an oecological system of which the human being was but one member. Disease was the outcome of ignorance; it was undesirable, unnecessary, preventable, and often curable. It was a barrier standing between man and his own self-selected goal and was therefore to be removed.

Science grew because it gave to man in increasing measure the power to control the forces of his external and social world. It grew because it came to be recognized that before individuals and nations could hope to realize their spiritual desires they must enjoy a certain level of material comfort and security. Science in application has made possible the material welfare of mankind. But it has done far more than this. It has given to mankind great hope and the possibilities of great dignity. The medical sciences have grown because man came to desire health and freedom from pain and anxiety, and because these sciences have given that for which the people yearned. Medicine has grown because it has shown itself to be one of the most potent tools that a society can use for the achievement of certain of its aims—the creation of a physical environment ridded of its disease-provoking agencies and propitious for the full growth and expression of man's inherent qualities.

For these reasons alone it is imperative that the student of medicine shall know what science is. He must be so attracted and impressed by the teaching to which he is exposed that he shall become and remain a scientist (in outlook at least).

Purposes of Biological Training

Biology, used as a branch of science to illustrate the whole, offers certain advantages. The student himself is aware of the biological nature of his own existence. Among the sciences it is biological science that seeks an understanding of the nature of human personality and answers to the questions—Whence came man, what is man, and what is to be his terrestrial destiny? The relative attractiveness of the biological sciences to the student is perhaps evidenced by the fact that failures in the first professional examination are invariably fewer in the case of zoology than in chemistry. Perhaps the student finds the examination easier because the subject is inherently more attractive (?). Other reasons for this difference—the ones that usually satisfy the chemist—can of course be adduced.

The content of the course and the method of its presentation are matters which have to be left to the teachers themselves. Doubtless they realize full well that the attractiveness of the apostle as a person is no less important in the matter of gaining adherents to a point of view or to a field of inquiry than is the beauty of the creed he presents and represents. If courses in zoology and botany respectively are offered by different university departments, as is usually the case at present, then it is imperative that the two should be most carefully integrated

Perhaps it is correct to say that what their colleagues of the later years of the curriculum desire of the teachers of the biological subjects is that the ultimate purpose of their teaching shall be:

(*a*) (in common with the physical sciences) to show that scientific knowledge is a special kind of knowledge, systematized and formulated and secured by the employment of certain particular modes of inquiry; to show that scientific inquiry rests on the warrantable assumption that among the circumstances and events in the world around us there is to be discerned an orderliness, a regularity, in the character or relations of certain classes of facts and events; to show that science is the product of human reason applied to the phenomena of nature and that it is that human interest and activity which

seeks to disclose this orderliness, this regularity, and to explain it; to exercise the student in the methods of science—the logical methods of reasoning, inductive and deductive, and the technical or technological methods of manipulation and measurement (including the elements of statistics); to exercise the student's curiosity in the stream of natural events that flows past him; to encourage his capacity for imaginative speculation (and his capacity to hold this in check); by every possible means to interest the student in the higher values of science—e.g., the aesthetic quality in scientific thinking, fairness in judgment, openness of mind, scepticism, intellectual honesty, dispassionate observation, critical discrimination; to contrast the relative values of reward in the form of wealth, security, social elevation, popular acclaim on the one hand and on the other the calm delight that comes from the contemplation of the harmonies of science and the exaltation that follows upon scientific discovery;

(*b*) (the special contribution of the biological sciences) to stimulate, excite, and satisfy the student by giving him an understanding of the theories of evolution, of the cell and of the gene, and of the impact of these theories upon human thought and action; to demonstrate the interdependence of Nature and nurture; to display the astonishing variety of biological inventions by means of which different types of living things function more or less efficiently—e.g., inventions relating to respiration, alimentation, reproduction; to trace the development of the animal society and to contrast the social life of animals with that of man; to demonstrate the essential harmony that exists between habitat and inhabitant and the effects of the disturbance of this harmony; to present the concept of the oecological system.

Much of what is here suggested might appropriately be offered in an arts course preceding the entrance of the student into the medical curriculum proper. Many of the topics listed may seem to belong to the territories of moral philosophy, logic, or aesthetics. But for the majority of medical students there is no such arts course, and so the responsibility for explaining these topics must be accepted by the teachers within the medical curriculum. There is no valid reason why the student should be the loser by this arrangement.

At present the complaint is all too commonly made by medical students that the courses in zoology and botany are a waste of the student's time; they are held to be useless because they do not seem to help in the cultivation of the bedside manner and because they postpone unnecessarily the contact between student and cadaver or patient. There is gross and grave misunderstanding here, and it is for the teachers of the first year to remove it. The mind of the medical is more important than are his medicaments.

A Privilege and an Adventure

Participation in the medical curriculum is a privilege, an adventure, a mounting excitement as knowledge is added to knowledge and understanding expands. If not, then it ought to be. What surely is required is that the first-year teachers shall hand on to those who follow students whose initial experience of the university has exceeded their wildest hopes, whose inclination towards medicine as a career has been strengthened, and whose mental outlook and habits have been profoundly affected as the result of their contact with science and the scientist.

It is a privilege to take part in the making of a doctor, since he can be such a force for good in open society. To bore him in his first year is as great a crime as to discourage his idealism in his last year. It is imperative in these most critical days to arouse his faith in science as a means of human and social betterment. We are afraid of the power with which science has endowed us. Out of this fear has emerged a widespread pessimism concerning human nature and human motives. In this course the student should be presented with the evidence which shows that man's dominion over the other species rests on his scientific knowledge concerning them. He should be invited to examine the evidence which points to the conclusion that, thanks to science and to science alone, it has become possible both theoretically and practically for mankind to build a world based on common effort for common good in which the powers which science gives will be used for beneficent purposes. He should be confronted with the proposition that the recent explosive growth of science has made it impossible to set limits to the directive capacity of man or to predict how far he may extend his dominion over his external world and over himself.

Believing in the perfectability of the human mind and loving his fellow man, the doctor, holding to the view that to expanding scientific knowledge there is no discernible limit, can do much to treat that most serious disease of mankind to-day, the pessimism which destroys man's faith in man and robs the future of all hope.

THE TEACHING OF ANATOMY TO THE MEDICAL STUDENT

BY

T. P. McMURRAY, M.Ch., F.R.C.S.Ed.

Emeritus Professor of Orthopaedic Surgery, University of Liverpool

Clinicians constantly complain that students on entering the hospital wards for the first time show a lamentable standard of anatomical knowledge. At first sight this would seem to be a severe condemnation of the teaching in the preclinical years, but there are certain factors which modify the value of the criticism. The clinician is, as a rule, a specialist in one branch of medicine or surgery, and his knowledge of the minute anatomy of the part of the body in which he is particularly interested is very extensive. If the roles were reversed, and the student were allowed to question the teacher on general anatomy, it might be that the report would be equally severe.

Because of the frequency with which these complaints are made, it is natural that the student's ignorance of the minute points of regional anatomy is accepted as proof of a weakness in the teaching of the subject.

Many attempts have been made to bridge the gap between the subject of anatomy as a basic science and its application to the clinical work which is the object towards which the training of the medical student is directed. In most schools young clinical teachers from the medical and surgical sides of the university have been appointed as lecturers in the anatomical department with the object of changing the bald anatomical facts into a living picture. These efforts have been to some extent successful, and the student is instructed by the clinicians in those points of anatomy which are considered to be of the greatest clinical significance.

The clinicians emphasize particularly the alterations in form and relationship which occur in the various organs as a result of their normal and abnormal functional activities, and they lay stress on the importance of the surface markings of the various organs and bony prominences.

In spite of these efforts at improvement the weakness still remains; the student takes little interest in this important

part of the subject, as he knows that the clinician will take no part in the examination, which will be conducted entirely by the anatomical teachers.

An experiment on somewhat different lines has recently been started in the University of Birmingham, where the subjects of anatomy and physiology have been integrated into one department. The idea is excellent; through this arrangement the bald truths of anatomy can be enlightened by the experimental work carried out in the physiological section, and the dead structure of the dissecting-rooms can be seen to function in a living medium.

Time Spent in the Anatomical Department

In spite of these efforts there are, however, certain questions which may reasonably be asked in regard to the teaching of anatomy. The first and most obvious of these is the problem of the time spent by the student in the anatomical department. Is time being given to anatomical instruction which could be devoted with greater advantage to other subjects in the medical curriculum? To answer this question is extremely difficult: every teacher in the medical faculty is convinced that his particular subject is not receiving adequate recognition in the student's training.

It is obvious that the student is not receiving too much instruction in anatomy, otherwise the criticism of the clinicians would not have arisen. The student cannot possibly know too much of that subject; it is just as important for the doctor to know every part of the human organism as it is for the engineer to know every nut and bolt of the machine for the repair and maintenance of which he is responsible. The only question, then, is whether the time spent in anatomical teaching could be rearranged to equip the medical student more fully for his life-work.

At present the greater part of the time spent in the anatomical department is devoted to dissection; the student must, during his attendance there, complete the minute examination of the whole body. Although this arrangement is very satisfactory, and gives both teacher and student a sense of completion, yet much of the routine work of dissection could be avoided without lowering the value of the instruction given to the student.

Dissection of at least one part of the body by each student is an essential step in his training. It is impossible to visualize correctly from drawings or photographs the exact arrangement of the fascia in its attachments to bone or in its intermuscular separations. These can be understood fully by completing the dissection of any one part; similarly, only by dissection can the student realize that the ligaments round a joint are not separate structures but are simply thickenings of the all-embracing fascial sheath of the limb. Again, in the dissection of any one part he can see the method of origin and attachment of muscle to bone, the method of entry of the motor nerve into the muscle belly, the splitting up of the cutaneous nerve branches, and the arterial and venous arrangements of the part.

These are only a few examples of the outstanding importance of dissection in the training of the student, but, once having accepted the necessity for dissection as an important factor in teaching, we are faced with the question of its extent.

Is it necessary for the student to dissect every portion of the body? There is so much which is common to all regions that it seems to be unnecessary to insist on a complete detailed examination of every part. Once the student has dissected and understood the arrangement of the more superficial structures of skin and superficial and deep fascia, with the emerging cutaneous nerves, in any region, it is comparatively easy, by the aid of diagrams and demonstrations, for him to understand the arrangement in other parts of the body.

A Suggested Rearrangement

A complete dissection of one joint with its articular surfaces, joint cavity, ligaments, and capsule will form the basis from which variations in other joints can be understood and appreciated. Muscles take their origin from bone, membrane, and fascia in the limbs as they do in the trunk and on the chest and abdominal wall; similarly, their methods of attachment to bone vary little in the different regions of the body. It is true that the arrangement of the organs, vessels, and nerves varies widely in the chest, abdomen, and skull, but even this problem can be overcome by the museum dissections, models, and drawings.

This suggested rearrangement would involve a considerable increase in the number of demonstrations which must be given if the standard of teaching is not to be lowered. The problem is how to maintain an equally high standard of general anatomical teaching and at the same time to improve the student's knowledge of those sections which are of the greatest clinical significance.

The obvious answer to this difficulty would at first sight seem to be an increase in the number of lectures; this would have the advantage of concentrating the attention of all the students on the same section. Although this method has some obvious advantages, it is not really the answer to the problem. The size of the classes and the distance of the student from the dissection which is being discussed tend to diminish the value of even the most perfect lecture.

Some lecturers have the ability to illustrate their teaching with clear, easily understood diagrams on the blackboard, but the best of these drawings fail to leave an impression on the student's mind equal to that gained by examination of the tissues in their normal relationship.

Lectures and blackboard demonstrations cannot replace, but can only implement, the value of dissection and visual examination of tissues. If, then, it is impossible adequately to replace the slow method of dissection by set lectures, can there be any rearrangement of lectures by which the student can obtain better instruction in an equal period?

The only method by which this desirable end can be achieved involves a considerable increase in the teaching strength of the department. Each teacher could take a small group of eight or at most ten students, and each part could be thoroughly and repeatedly demonstrated until in the opinion of the teacher an adequate standard of knowledge has been reached. All the different sections would then be fused into the general outline, and the relationships of each organ and tissue to its neighbours explained in the set lectures, which could thereby be reduced in number.

These suggestions would depend for their successful completion on an alteration of the outlook of at least some of the teachers in the anatomical department.

Divergent Views

The subject of anatomy consists essentially of a mass of facts each of which is of equal value in the mind of the pure anatomist, but from the standpoint of the clinician and of the training of the medical student some of these facts could be omitted from the course, while others could with advantage be stressed and elaborated.

A good illustration of this divergence of view is seen in the teaching of the musculature of the body. In the dissecting-room the student must learn the exact point and extent

of the origin of a muscle from bone and fascia with its course and relations to its point of insertion. He must also learn the nerve supply of the muscle; but its action, which is the most important clinical feature, is usually ignored or at most mentioned casually.

The clinical teacher, on the other hand, ignores the minute description of its bony attachments, stressing particularly the action of the muscle, and noting especially the fact that some muscles, like the biceps brachii, extend over two joints and therefore have a more complicated action than muscles such as the brachialis, which acts on only one articulation.

The anatomical teaching of the vascular system of the body is also so complicated and minute that the student is forced to learn in parrot fashion the innumerable named branches of the arteries. Thus the external carotid artery is described as starting from the common carotid opposite the upper border of the thyroid cartilage, extending upwards and forwards and then backwards to a point behind the neck of the mandible, where it divides into the superficial temporal and internal maxillary arteries.

In its short course the external carotid artery gives off eight named branches, whose course and relations must be memorized. These eight arteries in their turn give off a total of thirty branches whose names must also be remembered by the unfortunate student. Is it any wonder that as a result of this difficulty every student is fortified by the series of rhymes which help him to remember the first letter in the name of each branch?

Some Modifications

In suggesting a few modifications in the teaching of anatomy in the preclinical years we must avoid the mistake of trying to teach the subject in a specialized form. The broad conception of anatomical structure must always remain. The student must be taught the interdependence of each system on the others, and all attempts to describe e subject as one of watertight systems must be resisted. is wrong to suggest that a limited or first-aid course of anatomy would be sufficient to fit the student adequately for a medical career.

Nevertheless, there are some modifications which might be made in the anatomical curriculum, alterations which would not lessen the value of the course to the student and would make his subsequent medical training more simple. Of these suggestions the first and most obvious is the elimination of the uninteresting mass of detail which is of little practical clinical importance. The student should not be asked to take up a bone and map out by pencil or pen the exact limit of origin and insertion of every muscle and ligament to which it gives attachment.

To this suggestion the examiner holds the answer: so long as there is any possibility that he may be asked such detail the student must burden his mind with unnecessary material.

Further, there must be agreement between the clinician and the anatomist in regard to the amount of instruction which shall be given on pure anatomical grounds, as compared with functional and clinical details. It is unnecessary to teach all the details of muscular origin and insertion, but a sound working knowledge of these facts is necessary if the functional activity of a muscle is to be understood.

Much interest has been shown recently in the idea of instruction by means of radiographic demonstrations; these are of considerable importance in certain well-defined fields. Thus, radiographic pictures of the chest, abdomen, and joints are of considerable value, more especially in the case of the last-named in the recent innovation of movable pictures, but we must realize the limitations of this method of instruction.

Modifications can also be made with advantage in the teaching of the arterial and venous systems. These are vastly important to the student and to the doctor, but there can be no advantage in knowing all the names with which the subject is at present burdened. The main vessels must be known and their situation and relation to other important structures and organs fully realized.

Central Nervous System

The teaching of the nervous system could also be altered with considerable advantage. With a full knowledge of the nervous system the student will be able to understand many of the problems which he will meet after qualification. It is not enough to teach a student that the deltoid muscle is supplied by the circumflex nerve: he must also understand the area of the cord from which these fibres are eventually derived, and know the other muscles supplied from the same segment.

Neurology, which to most students of clinical medicine is a difficult subject, is largely a problem of anatomical localization. The apparent difficulties disappear when the structure of the central nervous system is understood.

Too little use has been made of the important subject of developmental anatomy. Thus when instruction is being given on the structure of the central nervous system it is easy for the student to grasp the relationship and the possible abnormalities which may be seen in this system if at the same time models are shown illustrating the various stages of development.

Similarly, it is not sufficient that the student should read of the development of the heart or intestine without giving him the help which is gained from a study of models of these organs at various stages. The structure of fully formed bone can be understood more readily if the changes which occur in these tissues can be studied in models and diagrams.

Anatomy is one of the most valuable subjects in the curriculum; no attempt should be made to reduce its importance, but a more complete integration of anatomy with the clinical subjects is not a difficult problem.

ON TEACHING PHYSICS TO MEDICAL STUDENTS

BY

D. W. SMITHERS, M.D., M.R.C.P., D.M.R.

Professor of Radiotherapy, University of London; Director of Radiotherapy Department, Royal Cancer Hospital

An attempt by someone who is concerned with postgraduate education to evaluate the present teaching of the basic sciences to first M.B. students is beset with difficulties. While it is true that one should be in a position to judge how well the students from a number of different schools and from several parts of the world have been equipped scientifically for the work they have to do as doctors, one is also out of touch with the trend of thought in the undergraduate schools and with the plans for improvement in the training that are already afoot. What appear to be defects may be reasonable compromises hammered out after long discussion, and what seem to be obvious overdue reforms may only be awaiting the moment when they are no longer quite impracticable. Voluntarily to

undertake the task of teaching one's grandmother how to instil the physical principles involved in extracting the contents of eggs is extremely rash. The incentive is a firm belief in the need for more science in medicine. By this I mean a way of thought, an approach to problems, and not merely what appears to the lay public so often as a rather terrifying and uncontrollable technology.

The process of development of medicine from a mediaeval art into a modern science is proceeding. There is no knowing where important implications to medicine may appear at any time from advances in the basic sciences. The study of mechanics led the anatomists to advance their interest in form to include an interest in function. An obscure draper in Delft, through a persistent interest in lens-grinding, was the first to see an animal "a thousand times smaller than the eye of a large louse" in a drop of water, and so laid the foundations of bacteriology and histology. As in the past so to-day: the introduction of artificial radioactivity in providing a new method of investigation by tracer techniques has started a new era of medical research.

The reason for inviting a radiotherapist to write about the teaching of physics is presumably that radiotherapists are so clearly concerned with the application of physics in medicine, and that they have been foremost in recognizing the need for the appointment of hospital physicists. Radiotherapists are not, however, alone in their interest in medical physics, the place of which is hardly given adequate recognition by astonishing statements such as the following which appeared in a leading article in the *British Medical Journal* in 1945: "At present the application of physics to medicine is limited to radiology, the electrocardiograph, and the encephalograph in diagnosis, and the somewhat empirical use of various forms of radiant energy in treatment; but it is highly unlikely that these represent more than a fraction of the contribution physics might make to human biology."

Physical methods of diagnosis and treatment have become indispensable in medicine and have so expanded in recent years and have covered so many branches that it was possible to publish in the United States a year before the above quotation was written an encyclopaedia of medical physics of 1,744 pages under 255 main headings listed in the table of contents (Glasser, 1944). The extension of the employment of physicists in general hospitals only awaits an initiative in other clinicians similar to that shown by radiotherapists; in fact, the latter have already established physics departments in most large hospitals which are ready and are waiting to be called on.

Educational Value of Physics

The importance of physics in medicine and the fact that the teaching of first-year students has been unable to keep pace with the advances cannot be seriously disputed. Before we judge the success or failure of present methods of instruction, however, we must have a clear understanding of what we want to achieve. It is all too easy to point out how much more is required, and all too difficult to reconcile the claims of the many subjects which compete for time on the already overloaded medical curriculum. If every sectional interest had its way years might be added to the training of the poor medical student, who only wants to be a doctor. The reason for teaching him physics should be to help to make him a good doctor first and to provide him with an appreciation of the practical applications of physics in medicine second. We should not forget, in considering the first, that technical ability may be an important professional quality and, in considering the second, that so many branches of medicine are open to each individual student that he is unlikely to deal personally in practice with more than a small fraction of the physical methods concerned. Teaching that does not help the student towards these ends should be ruthlessly eliminated on the grounds that the inclusion of any unnecessary work under the present conditions of strain in a medical education amounts to cruelty.

Anyone in daily association with a large and active department of medical physics employing nine physicists may be forgiven for stressing the importance of the practical application of physics in medicine, but no one who also consults with a number of doctors about the treatment of patients with cancer could deny the paramount importance of a sound general scientific education. The advancement of the practice of medicine demands that doctors receive a thorough training in the scientific method of logical, objective, dispassionate thought. To teach a medical student that the field of human knowledge is expanded by reason and experiment: that he should remain unmoved by plausible argument while retaining the capacity to accept new ideas, and so depend upon his own judgment; that when his facts are verified and his arguments tested he should proceed to apply his conclusions fearlessly—this is an achievement which rises far above the mere provision of technical proficiency.

Those combinations of qualities which go to make a good doctor and which are so hard to define are enriched and given purpose by a scientific outlook. The dissection of a problem to its fundamentals, the correlation and interpretation of the available facts, the conclusion uninfluenced by personal bias, add point both to the skill with which he applies his treatment and to the understanding and fellow-feeling that soften his conversation with his patients. We have too many fashions in medicine, too many new remedies which work wonders for a while, too many specialists whose diagnoses always lie within their specialty, and too many medical advocates of quack "cures" on the basis of one or two cases unusual in their limited experience but well within the bounds of normal variation.

It is reported (Shryock, 1948) as an example of the sad way in which treatment used to be based on mere assertions of the most dogmatic sort that Freteau, in the early nineteenth century, insisted on the necessity for venesection in certain conditions "on the ground of *two reported cases*, each susceptible of other interpretations than those he accepted" (the italics are not mine). Why pick on the nineteenth century when 1949 would do as well? We do not have to go so very far back in the correspondence columns of our medical journals for equally good examples. Doctors are not always less susceptible to convenient illusions than their fellows, nor are they less ready to produce rationalizations to preserve for themselves their appearance of reasoned thought and logical action. The laudable desire to save the medical student from some of the rigours of the syllabus, to get down to "the fundamentals of medicine" and away from all this "pure physics," must not be allowed to interfere with his essential, basic scientific education. Physics and mathematics are particularly valuable as a background training in scientific thought and method.

Medical Physics

Having insisted on physics for its basic must we therefore necessarily insist on a physics similar to that planned for the el of physicists? Surely a greater concent

physics will serve our purpose just as well and at the same time add interest and practical advantage. The undergraduate should learn to appreciate the use of physical methods in medicine and acquire a basic knowledge on which to build should he later take up some branch which is closely associated with a particular form of medical physics. It may be as well that the basic sciences should not seem to be too well defined; medicine has no interest in artificial barriers between the sciences, and physical chemistry and biophysics cannot be ignored because they have been arbitrarily placed on some borderline. We shall certainly not solve the real problems of the lengthening syllabus, the urge to get on with the things that will be useful, and the need to eliminate the inessential by insisting on the *status quo*.

Once the student has embarked on his medical career the continuation of his scientific education should surely be made an integral part of his training rather than a preliminary to it. The medical student sets out to do medicine; he regards a good deal of what he is taught in his preclinical course as being divorced from this object. It is too often merely an obstacle in the path of his progress towards matters of real interest. He has to-day to overcome considerable difficulties to be allowed the opportunity to start at all, and at this stage is eager for instruction in subjects that seem to him to have an obvious medical application. When you start out to heal the sick it is a little discouraging to find yourself confronted by a Wheatstone bridge and a post-office box.

Dr. Henry Yellowlees (1946) starts his admirable and delightful book with the sentence, "I suppose that the most significant, if not the most memorable, day of a medical student's career is that on which he finally emerges from the preclinical period, and I have always felt that the occasion of his first introduction to clinical work might well be marked by some appropriate ceremony." I think that this is a true picture of the position, but it contains some reflection on our method of presentation of the basic sciences as medical subjects.

Adjustment of the Syllabus

Postgraduate students embarking on a physics course for a diploma in medical radiology can be heard one after another denying familiarity with the physics that they were taught so few years before. No hospital physicist "assumes a knowledge of physics equal to that of the first M.B." whatever the regulations may say, because he knows from sad experience that he can do no such thing. This is some indication of the failure to ensure that the training does at least consistently provide a sound though elementary knowledge of physics. Is it possible that the reason so many retain so little is that their interest was not engaged; and could the general educational result have been achieved with medical physics of more interest to the student and a greater degree of usefulness to him during his clinical training?

If we assume that the present methods do achieve their main object of developing a scientific outlook and promoting a way of thought, giving due allowance to the varied abilities of the students to absorb such teaching, then reform must be cautiously applied to see that none of this is lost. If we assume that they do not achieve even this end, then reform is urgently needed. There would seem to be some reason for doubt whether the present arrangements of the teaching of physics are in fact nicely adjusted to produce the desired result. No emphasis is placed in the syllabus on the development of the all-important attitude of mind; this is left to take care of itself in the general classical approach to the subject that is laid down, or rather is left to the individual teachers on whose varying knowledge of the needs of medicine and whose ability to impart an outlook to the student all ultimately depends. Some, at least, seem concerned only with the elementary details of heat, light, sound, electricity, and magnetism.

The practical utilitarian side of the instruction appears shyly here and there in the syllabus with the mention of osmosis, spectacles, microscopes, ophthalmoscopes, radioactivity, and thermionic emission. That no real importance is attached to these concessions to those who have demanded more direct application of the prescribed syllabus to medicine is shown in the list of exemptions which allows a boy from school to avoid all such instruction. The introductory paragraph of the syllabus of the University of London for "Physics (including Mechanics)" does not say, "The subject is to be treated as a basis for the development of a critical, reasoning, scientific outlook and illustrated as frequently as possible by means of direct practical examples of the applications of physics in medicine; a knowledge of mathematics on the part of the student is an inestimable advantage in attaining this object, the experimental approach being the only other method likely to be successful." Instead there appears the rather dreary sentence, "The whole subject is to be treated in an elementary manner, the mathematical development in no case extending beyond a knowledge of quadratic equations and elementary trigonometry."

It has, I believe, been suggested that the first M.B. might be abolished and that instruction in chemistry, physics, and biology be given along with that in anatomy and physiology in one preclinical course. More time is wanted for the second M.B., and it is thought to gain it at the expense of the first. The time would presumably be gained by the elimination of much of what is now taught in the basic sciences and regarded by some as unnecessary, and what remained would be more closely related to practical, everyday medical needs. If every student received a sound scientific training at school, if anatomy and physiology were not allowed to swamp the chemistry, physics, and biology that remained, and if teaching were done imaginatively and largely by the experimental method, using direct clinical applications for illustration, there would be much to be said for the suggestion. The student would start off doing something more nearly related to medicine; he might better appreciate the need for the physics he was being taught. There are, however, a lot of "ifs" concerned. I do not know how such an arrangement would work, but while fundamental changes are being discussed there are still reforms which surely should be made at once.

Suitable Instructors

The teaching of physics to medical students should never be solely in the hands of a university physics department, but should include instruction from those with personal practical knowledge of the medical applications of physics and who themselves engage in research in physics in relation to biology or medicine. There is a growing band of hospital physicists available who would benefit from a closer contact with medical students and also from the necessity to review the applications of their branch of science to medicine on its broadest basis. There should be no exemptions from a course of this kind. Hospital physicists could produce many fascinating subjects for inclusion in it. Some knowledge of radioactivity, of the use of

radioactive isotopes as tracers in the investigation of physiological and pathological problems, and of the use of a Geiger–Müller counter as a clinical instrument are obvious examples. It is not difficult at the same time, for instance, to convey something of the potentialities of the quantitative method, something of present ideas of the nature of the atom or the ways in which experimental confirmation of theory has been obtained.

Last year I was fortunate enough to see the results of an exercise set by Dr. Joseph Hamilton to a student class in the University of California at Berkeley in which each student was required to set down in detail an account of an experimental investigation that he would like to carry out with a radioactive tracer material and that had not been suggested before in the literature. Nearly all were reasoned, practical, original suggestions, and some were so well presented and of such merit that the opportunity of carrying out the experiment was being provided to these students. It would be hard to find a better example of the use of a method of applied medical physics as a means for promoting a scientific outlook. It is difficult to believe that such a result could be obtained with the methods of training students in operation in most schools in this country at the present time.

Practical Applications

Illustrations of the application of physics in medicine naturally occur to me primarily in the field of radiation, but many others can be found. Some of the applications of optical principles, such as the measurement of erythrocytes by the haloes they cause around a source of light, or microscopy from the optical microscope to the fascinations of the electron microscope, where a virus may be shown by means of a golden shadow, are good examples. Electronics is invading medicine on a large scale and provides possible demonstrations for the student in such varied fields as neurophysiology, the measurement of radiation, the use of hearing-aids, electrocardiography, muscle-nerve stimulation, colorimeters, *p*H meters, and even the demonstration of surgical operations by television.

An obvious illustration in surgery is the importance and means of counteracting the physical factors that interfere with respiration and circulation when the chest is opened. The dermatologist may be interested in the physical forces which produce alterations in skin pigment, the psychiatrist in electric-shock therapy, the ophthalmologist in the spectral sensitivity of the various parts of the retina and the methods of investigating night-blindness, the haematologist in electrophoresis, the orthopaedic surgeon in the trajectories of stresses in bone, and the otolaryngologist in the complications of vestibular mechanisms.

The difficulty is not to find illustrations but to distinguish amongst the wealth of material available those most likely to hold the student's interest and provide him with an appreciation of the underlying physical principles concerned, while unobtrusively developing his powers of critical examination of a problem and his desire and ability to test a theory by experiment—in fact, providing him with the capacity for logical, impersonal, objective thought.

SIR WILLIAM GOWERS

Sir William Gowers. By Macdonald Critchley. (Pp. 118; illustrated. 17s. 6d.) London: William Heinemann Medical Books. 1949.

Dr. Macdonald Critchley's life of Sir William Gowers, who was born in 1845, records the chief events of his career, illuminates them with the reminiscences of those who were privileged to be his pupils, and reviews his contributions to medicine. He was born the son of a Hackney shopkeeper, and it was probably the accident of his father's early death and his widowed mother's migration to the neighbourhood of Oxford that set his foot on the first rung of the educational ladder at Christ Church College School. An apprenticeship to a general practitioner in Essex was his entry into the profession to which he was destined to contribute so much. Thereafter University College Hospital and subsequently the National Hospital made up the sphere of his activities. He played no great part in medical affairs: neurology filled his working life, and hobbies, especially shorthand, occupied his spare time. He died in 1915.

Gowers will be remembered as a great clinical observer. Dr. Critchley points out that the early descriptions of many of the nervous diseases which we recognize to-day with confidence are due to his acumen. That this has not been more generally recognized in the past is due to the fact that many such descriptions were given casually in the course of his writings and it was often left to subsequent observers to attach a label to conditions which Gowers had discovered.

Dr. Critchley has written a valuable memoir which is short enough to make the reader wish for more. Ten illustrations add to its interest, and it includes a bibliography.

RUSSELL BRAIN.

PIONEERS IN ORTHOPAEDICS

On the Contributions of Hugh Owen Thomas, Sir Robert Jones, and John Ridlon to Modern Orthopaedic Surgery. By H. Winnett Orr, M.D.; supplement by Arthur Steindler, M.D. (Pp. 253. £1 5s.) Oxford: Blackwell Scientific Publications.

These three men, prominent in their generation, have added much to orthopaedic surgery, and a critical examination of the work of any one of them would be sufficient to satisfy most writers. Dr. Orr has wisely not attempted to judge the value of all their contributions to orthopaedics, but has confined himself largely to Thomas's writing on rest, and the reactions of Jones and Ridlon to these principles. It is for this reason that Jones and Ridlon appear not as original workers themselves but rather as pale moons reflecting the light of the sun. The book enables the reader to obtain a picture of the relations between the three men, and it brings to the notice of the profession once again the great advances made by Thomas and the difficulties he encountered.

Dr. Orr's style of writing leads on occasion to some difficulty. He does not finish his remarks on one personality before discussing others, and this results in a certain amount of confusion which could readily have been avoided. He rightly criticizes the many modifications and improvements of the Thomas splint that have been suggested during and between the two world wars, and states that it would have been preferable if the authors of these suggestions had learned how to use the splint in the correct manner. Directly after this condemnation Dr. Orr explains that "the use of skeletal fixation pins (not wires) in plaster of Paris represents the only substantial improvement in the technique for maintaining correct length—position—and rest—since Thomas himself."

It is unfortunate that with a subject in which the facts could be so readily confirmed there should be a few obvious mistakes. For example, Thomas was not trained by his maternal uncle Owen Roberts, of St. Asaph, at the Liverpool Workhouse Hospital, as stated in the text, and it is obvious that Dr. Orr meant Sir Astley Cooper and not Sir Ashley Cooper. It is hard to define the exact character of this book: it includes many extracts from other authors and follows closely their opinions.

T. P. McMURRAY.

Reviews

SURGICAL COMMENTARY

A Companion in Surgical Studies. By Ian Aird, Ch.M., F.R.C.S. (Pp. 1,060. £3 3s.) Edinburgh: E. and S. Livingstone. 1949.

This is a new and attractive book, and the author is to be congratulated on choosing a happy title and on providing such a pleasant and useful companion for the senior student and postgraduate. The volume represents an enormous amount of work, for there are over a thousand pages of reading matter, ten thousand references, and ten thousand items in the index. It is largely based upon lecture notes and is certainly well up to date. In at least one place there is over-emphasis on a subject of minor interest—there are four and a half pages devoted to pre-auricular fistula. Some of this space might well be sacrificed to make room for a more detailed account of the relative value of the tests of renal function, or some other subject of similar importance.

The book is well written and is all from the one hand. It not only contains the basic information on all the problems with which it deals but gives finger-posts to the sources of information which the student must consult if he wishes to improve his knowledge further. In the introduction the author says, "It is hoped that this book will be found convenient for employment in the hospital ward and ante-theatre, no less than in the study, as a kind of commentary to the clinical illustration which the ward and operating theatre afford. For this reason and for economy of space diagrams have been entirely excluded." This was probably a wise decision, though it is difficult to understand the operation for cleft-palate (Wardill's) in the absence of a diagram.

It is unfortunate that the author felt it necessary entirely to omit the subjects of fractures and orthopaedics from his book, and it is difficult to accept one of his reasons for doing so—that "the gap between general surgery and the ... lized surgery of the skeleton is so wide." Surely it ught not to be. Every candidate for the higher surgical xaminations is required to have a sound basic knowledge of these subjects, and most surgeons would agree with the view that every general surgeon should have at least a working knowledge of them. The total exclusion of these subjects leads to serious difficulties for the student, for though he will find a good account of the paraplegia due to Pott's disease of the spine he will look in vain for an account of the main symptoms of that disease; he will read that osteitis deformans may attack the lower jaw but fail to find any general account of Paget's disease of bone. He will even get sound information on the treatment of a wound which involves a bone but have to obtain the details of the treatment of the fractured bone elsewhere. Another hundred pages giving the main facts of these two subjects, with appropriate references, would make this book almost a necessity for the postgraduate student.

V. ZACHARY COPE.

ILLUSTRATIONS OF SURGERY

Illustrations of Surgical Treatment, Instruments and Appliances. By Eric L. Farquharson, M.D., F.R.C.S.Ed., F.R.C.S. Foreword by the late Sir John Fraser, Bt. Third edition. (Pp. 391; illustrated. £1 5s.) Edinburgh: E. and S. Livingstone. 1949.

There is much to be said for the pictorial method of teaching in an intensely practical subject like surgery. Not that pictures, even when accompanied by good descriptive matter, can act as substitutes for clinical experience, but in the student's comparatively short period of training there are many surgical techniques which he has no opportunity of seeing. In this connexion Mr. Eric Farquharson's book fills an obvious gap. The work is already well known, the present being the third edition. The reader must realize that it limits itself to certain orthopaedic conditions, fractures, closed injuries, and deformities, and is mainly concerned with plaster technique. The second section, which consists of numerous illustrations of surgical instruments and appliances with short descriptions of their uses, covers a much wider field. The author has been unduly conservative in his choice of instruments, but this may be of advantage from the student's point of view.

The illustrations have been carefully chosen and are well reproduced, so that a good and clear conception can be obtained of the procedures depicted. The text contains many useful hints which house-surgeons will find of value when they handle their first cases.

This is a book which can be recommended to the senior student and the junior surgeon as a trustworthy guide, especially in fracture work. Some of the sections have been revised, and the price has not been advanced since the last edition was published in 1942.

NORMAN C. LAKE.

ANAESTHETICS FOR STUDENTS

Anaesthetics for Medical Students. By Gordon Ostlere, M.A., M.B., B.Chir.(Camb.), D.A. With foreword by C. Langton Hewer, M.R.C.P., F.F.A.R.C.S. (Pp. 108. 7s. 6d.) London: J. and A. Churchill. 1949.

This book is an attempt to explain to medical students how an anaesthetic may be administered with safety to the patient and satisfaction to the surgeon. It is written in a pleasant, easy, and informal style, and is short, concise, and to the point. Its objects are certainly achieved.

There are some anaesthetists, however (of whom I confess myself one), who consider anaesthetics to be a postgraduate rather than an undergraduate study, and from this viewpoint the book is perhaps too inclusive. However, assuming that medical students do require to be taught the details of intravenous techniques, closed circuit methods, and local and spinal analgesia, this book does convey the necessary information in a readable way, eminently suited for study "in the bus, or while awaiting the entrance of an unpunctual surgeon." It includes all the important facts without being too dogmatic or detailed, and the student who knows this book well should be able to tackle any question on anaesthetics which he is likely to meet in his qualifying examination.

R. BLAIR GOULD.

TEXTBOOK OF MEDICINE

Medicine. By A. E. Clark-Kennedy, M.D., F.R.C.P. Volume 2. (Pp. 522. £1 5s.) Edinburgh: E. and S. Livingstone. 1949.

The second volume of Dr. Clark-Kennedy's book is concerned with diagnosis, prevention, and treatment. Its six chapters are entitled: Clinical Diagnosis, Special Investigations, Disturbances of Function, Reactions of the Mind, Pathological Processes, and The Practice of Medicine. This is not a textbook of medicine containing the factual knowledge necessary for passing examinations or the practice of one's profession. The subjects are discussed in a broad manner as a series of essays, and the text makes very pleasant reading. A great amount of material is covered, and new light is thrown on many of the infirmities to which the mind and body of man are heir. No one can read this book without having his interest stimulated and his outlook broadened.

The titles of the chapters do not alone indicate the many subjects considered, but these are related in subheadings. The prospective reader may be interested in a short selection of these—The Urgent Case, The Easy Case, The Difficult Case, *X*-ray Shadows, Looking into the Body, Tests of Function, Fever, Reactions of the Mind, The Doctor, The Family, and The State.

We must expect generalizations rather than details in a work of this type, and the information given about any one subject is necessarily somewhat meagre. For example, the use of "lipiodol" in the diagnosis of pulmonary conditions is dismissed in half a page. A barium enema is said to be "more time-consuming and more unpleasant than a barium meal. The information gained is more expensive and on the average less reliable." This must, however, depend upon what we are

looking for; if the barium enema is able to reveal a growth of the colon in an operable stage, and the barium meal fails to do so, the comparison is somewhat unfair. In the section describing the *x*-ray appearances of the heart we learn that when the patient is screened in the postero-anterior position "the right border of the heart with the patient in this position is formed below by the right ventricle." Readers may not be in agreement with this.

The book will make a wide appeal, for it expresses the inarticulate and ill-formed thoughts of many a seasoned practitioner of medicine.

G. E. BEAUMONT.

CARDIOLOGY AND GENERAL MEDICINE

An Introduction to Cardiology. By Geoffrey Bourne, M.D., F.R.C.P. (Pp. 264; illustrated. 18s.) London: Edward Arnold.

Patients with diseases of the digestive, pulmonary, and nervous systems may present with symptoms suggesting heart disease, and many diagnoses will be missed unless the cardiologist has a considerable familiarity with general medicine. This theme is predominant in Dr. Bourne's book.

The author has described the chief aspects of cardiovascular disease: opening sections on clinical methods are followed by chapters on heart failure, diseases of the myocardium, and disorders of rhythm. Articles on valvular and vascular diseases of the heart are admirably suited to the needs of the undergraduate student of cardiology, though "angina innocens" is not a term which has commended itself to most cardiologists. No doubt the inevitable delay between writing and publication accounts for the statement that atheroma is responsible for 60% of cases of aortic stenosis in the British Isles. Recent investigations have emphasized the role of rheumatism in the majority of cases. Such points do not, however, detract from the value of the book, which has throughout the ring of personal experience and which should inculcate in budding physicians and cardiologists an understanding of the fundamentals of medicine from the cardiologist's viewpoint. The continuity of the book is impaired by its derivation from lectures, but it demonstrates throughout the principles upon which cardiological diagnoses are based.

K. SHIRLEY SMITH.

"EDEN AND HOLLAND"

Eden and Holland's Manual of Obstetrics. By Alan Brews, M.D., M.S., M.R.C.P., F.R.C.S., F.R.C.O.G. Ninth edition. (Pp. 796; 36 plates, 12 in colour, and 405 illustrations. £2 2s.) London: J. and A. Churchill. 1948.

This work has always been acknowledged as one of the finest examples of a British textbook, for the publishers have used the best available paper and print and have been lavish with illustrations, while the authors, apart from being men of great academic distinction, have been able to write with clarity and precision. Mr. Alan Brews can be congratulated on the efficiency with which he has revised the book, and his powers of expression are at least equal to those of the previous authors. Moreover, he has shown skill in picking out from the literature which has been published since the last edition those contributions which deserve inclusion.

The new volume can be regarded as a full and up-to-date account of obstetrics as practised in Great Britain. It will be universally welcomed, particularly by postgraduate students working for higher examinations. Although the book is long it is not easy to see how the size could be reduced, for it is of primary importance in a textbook of this kind that full references should be made to original work. Indeed, it may be argued that the book should be expanded so that in time it can rival the great American textbooks.

The new diagrams are not always of the same high quality as those of previous editions, otherwise there is little to criticize. The success of the new edition is certain.

WILFRED SHAW.

PRACTICAL OBSTETRICS

Handbook of Midwifery. By Margaret Puxon, M.D., M.R.C.O.G. (Pp. 326. £1 5s.) London: Sylvio Publications. 1949.

Since the end of the war a number of books on practical obstetrics and gynaecology have been added to the literature. Many of these take the form of revision manuals for the general practitioner and those wishing to revise for higher examinations. Dr. Puxon's book is of this type: she presents a practical manual of obstetrics with emphasis on the normal. The subject is discussed in reasonable detail and the text is up to date. The style is that of a book of reference rather than a textbook, and the synoptic treatment of many of the sections makes it as a whole not very readable.

The book is marred by some errors of fact and by the doubtful value of some of the advice contained in it. For example, the level of the blood urea is not always raised in chronic nephritis in pregnancy, and in severe pre-eclampsia the baby is often small, not of normal size, as stated. The administration of pethidine by the intravenous route is recommended, though it is noted that collapse may occur. Surely such dangerous advice would be best omitted altogether, since the drug can be given safely and with reasonably rapid effect by the intramuscular route. The use of ergometrine to induce labour has only to be mentioned to be condemned as extremely dangerous in any circumstances. The dose of 0.5 mg. of ergometrine intravenously for postpartum haemorrhage is unnecessarily high and liable to cause side-effects.

The chief faults of this book are that it attempts too much in too small a compass and that it suffers in many instances from lack of illustrations. These shortcomings detract to some extent from its real merits of completeness and sound practicality.

JOSEPHINE BARNES.

SYMPTOMATIC DIAGNOSIS

Symptoms in Diagnosis. By Jonathan Campbell Meakins, C.B.E., M.D., D.Sc., LL.D. Second edition. (Pp. 542; illustrated 42s.) London: Baillière, Tindall and Cox. 1949.

Like Disraeli, many medical authors hate definitions, and Dr. Jonathan Meakins makes no attempt in this book to define the meaning of "symptoms" beyond the statement that they are "the patient's way of telling his story." This omission may explain why much of the work is concerned with phenomena generally regarded as physical signs. This is not a true defect, however, for the division of the subjective and objective phenomena of disease into symptoms and signs is patently artificial, the artificiality extending to books which undertake to consider them separately.

The author follows the customary pattern, considering in successive chapters the body's various anatomical and physiological systems and the symptoms which arise in connexion with them. The four final chapters on the eye, the ear, nose, and throat, the nervous system, and symptoms in psychiatry are contributed by specialist colleagues. Dr. Meakins's great experience and erudition are reflected in the mass of factual information presented; it is not clear to what audience the book is addressed, but the detail may be overwhelming for the student. In some sections rarities are accorded a disproportionate amount of space, and in others forbidding lists of causes will deter the faint-hearted. These minor criticisms do not detract from the general excellence of the text, and the discussions of cyanosis and dyspnoea are of particularly high standard.

The inevitable systematic arrangement tends to destroy cohesion, and symptoms which cannot be allocated to any one system elude consideration—there is, for instance, no discussion of fever. It is also disappointing not to find a section concerned with the technique of eliciting symptoms, for a chapter on history-taking would have given the book a unity that at present it lacks. There are signs of hurried proof-reading, and the reader's pleasure is sometimes marred by a turgid literary style: the author of *Plain Words* would not have approved of "Increased fragility (of bone) is demonstrated by a predilection to spontaneous fractures."

R.

A BEDSIDE HANDBOOK

Bedside Diagnosis. By Charles Mackay Seward, M.D., F.R.C.P.Ed. With foreword by Sir Henry Cohen, M.D., F.R.C.P. (Pp. 372. 17s. 6d.) Edinburgh: E. and S. Livingstone. 1949.

Dr. Seward points out the wide gap that exists between the symptoms complained of by the patient and the contents of the usual textbook of systematic medicine, and he attempts to help the student bridge this gulf. The book opens with sections on psychogenic symptoms and pain, but the remainder of the text consists of 20 chapters discussing the implications of single signs or symptoms. Each chapter is prefaced by a list of the common causes of the symptom in question; the underlying physiological disturbance is described whenever possible; and suggestions are made for shortening the list of possible diagnoses by analysis of the presenting complaint. There follow a brief description of the diseases responsible for the symptom and an account of the important investigations that may be required in diagnosis.

The author's plan is sound, and is that followed by many clinical teachers in the wards. The information is accurate; where statistics are given they are well chosen; and the work bears the stamp of a practical physician throughout. The book has flaws, though it is only fair to add that these are the result of its brevity, for even the common diseases are too numerous and too variable to be adequately described in such small compass. A notable weakness is lack of information on the diagnosis of diseases of the nervous system, common conditions such as disseminated sclerosis, hemiplegia, and epilepsy not being mentioned. But as the book is intended as a guide to the principles of diagnosis rather than a work of reference such omissions can be forgiven. The publishers are to be congratulated on the production, and the price is not high by to-day's standards.

SIDNEY TRUELOVE.

The twelfth edition of *Clinical Methods*, by Sir Robert Hutchison and Dr. Donald Hunter (pp. 484; 17s. 6d.; London: Cassell, 1949), has undergone a thorough revision, for which the authors have called on the assistance of Dr. R. R. Bomford. Some of the methods and phrases that gave an air of antiquity to parts of the previous edition have been eliminated, and the text now incorporates modern work on haematology, liver function tests, and elementary radiology. Some teachers will note with displeasure that the third and fourth heart sounds have made an appearance in the book, and it is surprising that a long description of the polygraph has been retained in a practical volume of this sort. The format has been altered, and the use of large and small type will help the student considerably in the difficulty he faces with all his textbooks—the selection of the leading facts from the less important details. The illustrations have been greatly improved, particularly those of urinary crystals. This edition will be found easier to read and to remember than its predecessor, and the book remains equally important to candidates for Membership and the M.B.

Dr. F. M. R. Walshe's *Diseases of the Nervous System* (pp. 359; 17s. 6d.; Edinburgh: E. and S. Livingstone, 1949) made its first appearance as recently as 1940, which may be a matter of surprise to many of its readers. It has now become a well-established textbook and occupies as important a place in the student's reading as many senior volumes. In the sixth edition the text has everywhere been brought up to date. The chapter on neurosyphilis has been rewritten and the sections on acute poliomyelitis and intracranial abscess enlarged. The short chapter on psychoneuroses has been retained, and there is a useful scheme of examination of the nervous system at the end of the text. Dr. Walshe should relieve the student who carefully reads this book of the anxiety with which he usually contemplates a neurological case in the final examination.

In their *Elementary Atlas of Cardiology* (pp. 108; 99 illustrations; 12s. 6d.; Bristol: John Wright, 1948), Drs. Wallace-Jones, Chamberlain, and Rubin have put together a series of electrocardiograms illustrating abnormalities of rhythm and of myocardial function. These are the standard records used for undergraduate teaching; they and the accompanying legends fulfil this purpose excellently. The authors have perceived that even in an elementary textbook chest leads must be mentioned, and they include IV R, IV F, and CR1. It is not clear why both of the first two are described when some other lead instead of IV F, such as CR6 or CR7, would have given additional information. The book includes a section on the radiography of the heart. This achieves a succinct presentation of the principal abnormalities, but the illustrations are not of high quality.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Text Book of Surgery. By P. Kiely, B.Sc., M.D., M.Ch., F.R.C.S. (Pp. 1,184. 45s.) London: H. K. Lewis. 1949.

The Evidence for Voluntary Action. Edited by Lord Beveridge and A. F. Wells. (Pp. 343. 16s.) London: Allen and Unwin. 1949.

The Value of Hormones in General Practice. By W. N. Kemp, M.D. (Pp. 115. $3.) Minneapolis: Burgess Publishing Company. 1949.

The Substitute Family. By F. Knight, L.H.D. (Pp. 84. 3s. 6d.) London: The Convocation Lecture, 1949, of the National Children's Home. 1949.

What is Psychoanalysis? By E. Jones, M.D. (Pp. 126. 7s. 6d.) London: George Allen and Unwin. 1949.

The Yearbook of Psychoanalysis, 1948. Vol. 4. (Pp. 356. 30s.) London: Imago. 1949.

Understandable Psychiatry. By L. E. Hinsie, M.D. (Pp. 359. 22s. 6d.) New York: The Macmillan Company. 1948.

A Review of Nursing. By H. F Hansen, R N., M A. 6th ed (Pp. 866. 21s.) London: W. B. Saunders. 1949.

The American Nurses' Dictionary. By A. L. Price, B.S., R.N (Pp. 656. 19s.) London: W. B. Saunders. 1949.

"Doctor Himself." An Unorthodox Biography of Harry Roberts, 1871–1946. By W. Stamp. (Pp. 163. 10s. 6d.) London: Hamish Hamilton. 1949.

The Principles of Chiropody. By J. H. Hanby, F.Ch.S., and H. E. Walker, F.Ch.S. (Pp. 383. 21s.) London: Baillière, Tindall and Cox. 1949.

Tablet Making. By A. Little and K. A. Mitchell. (Pp. 121. 15s.) Liverpool: The Northern Publishing Company. 1949.

Tax Tables, 1949-50. By G. Whillans, F.I.B. (3s. 6d.) London: Butterworth. 1949.

Précis des Maladies Allergiques. By Pasteur Vallery-Radot. (Pp. 223. 550 francs.) Paris: Editions Médicales Flammarion. 1949.

Le Sexe. By V. Dantchakoff. (Pp. 210. No price.) Paris: Presses Universitaires de France. 1949.

Thrombo-Phlébites Cérébrales. By R. Garcin and M. Pestel. (Pp. 135. 600 francs.) Paris: Masson. 1949.

Von der Angst der Kranken. By K. Scheele. (Pp. 75. M. 4.80.) Stuttgart: Georg Thieme. 1949

Über die neuen Strahlenschutzregeln. By H Graf. (Pp. 72. M. 4.) Stuttgart: Georg Thieme. 1949.

Über die Anzeigepflicht des Prosektors wegen Ärztlichen Verschuldens. By F. Feyrter. (Pp. 88. 12s.) Vienna: Wilhelm Maudrich. 1949.

Grundriss der Allgemeinen Zoologie. By A. Kühn. (Pp. 281. M. 18.) Stuttgart: Georg Thieme. 1949.

Die Bazillenruhr. By L. Roemheld. (Pp. 125. M. 10.80.) Stuttgart: Georg Thieme. 1949.

Leitfaden der Neurologie und Psychiatrie. By W. Kurth. (Pp. 305. M. 22.) Stuttgart: Georg Thieme. 1949.

Die Erkrankungen der Endokrinen Drüsen. By A. Oswald. (Pp. 580. 58 francs.) Berne: Hans Huber. 1949.

Uremia y Seudouremia. By J A. Bofill. (Pp. 168. No price.) Barcelona: Ediciones Byp. 1949.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY SEPTEMBER 3 1949

INSTRUCTION OR EDUCATION?

In this Educational Number our distinguished contributors are all discussing from different points of view the same question. This is a question which has been asked since ever there was a medical curriculum to reform. Is it possible, by integration, to compress the present curriculum, overloaded with instruction, within limits that will no longer stultify attempts at education? In different keys, but in harmony, our contributors say yes. All are agreed that medical students must be "educated" and not merely tutored, or else when in practice in an increasingly instructed and science-conscious community their prestige will rightly sink.

The most serious complaint voiced to-day is that as the student passes from the premedical to the preclinical period and thence to the wards he appears to have learnt little of his professed subjects and forgotten more. The explanation generally offered is that subjects are presented in such a way as to lack demonstrable value for the student's aim of becoming a doctor; he thinks them futile and frustrating. Some blame, of course, is laid at the door of examiners, but more at the lack of unity of the curriculum. Chemistry, physics, anatomy, biology, and even physiology appear remote from the student's objective, or so the critics allege. One means of amendment proposed is the fusion of anatomy and physiology—now in the programme of one school, Birmingham—and another the integration of all the chemistry from first to sixth year under one educational head, as at the Middlesex. Perhaps even that is not enough: is there not room for the inclusion of pharmacology with chemistry and for its proper relation to general medicine? No doubt other co-ordinating experiments will be tried as pilot endeavours in other schools. The right method will only be reached by trial and error—in fact, by the "experimental" method.

A partial solution of difficulties might be found in a co-ordinating committee, or perhaps even a dean-dictator, of education, whose purpose would be to assemble all the staffs, first, second, and third stage teachers, and devise a composite course that would excite the student's expectations and make clear to him that however devious the path plotted for him it leads to the goal. As Professor Smithers says, "The reason for teaching him physics should be to help to make him a good doctor," and adds that "the best people to teach physics are perhaps those who themselves engage in research in physics in relation to biology or medicine." Professor Dodds points out that it might be stimulating even for first-year teachers of inorganic chemistry to feel that they kept touch with their students up to and after qualification, and had an interest in the reputation of the profession in the community. "What surely is required," writes Professor Crew, "is that the first-year teachers should hand on to those who follow students whose initial experience of the university has exceeded their wildest hopes."

There have been many proposals for improving the method by which doctors are trained, but it is unusual, to say the least, to find so plainly stated the need to improve the teachers as well as the taught and the teaching. It is indeed remarkable not so much that clinicians never have sought instruction or training in the art of teaching, as that the men of science, the physiologists, the research workers, who can transform themselves into clinicians overnight by the acceptance of a chair, have not been prompted by their daily practice of the scientific method to take a course in pedagogy. The methods used by educationists to teach the teacher are described in this issue by Professor W. R. Niblett. He urges co-operation between institutes of education and schools of medicine, and here, perhaps, one of the matters to be inquired into might be the training of doctors in the art of teaching. Teaching, however, is a small part of the great burden that professors now carry. It is too much to expect that research, clinical experience, a competent understanding of intimate human relationships, administrative wisdom, and the patience of a good committee-man can all be combined in the same person. One way or another the ardours of research, the art and practice of educating, and the pursuit of planning must be shared. An older and experienced director of education might share responsibility with a younger research professor, or perhaps middle age for research and youth "to teach the young idea how to shoot" and, *pace* Francis Thompson, not "to pour the fresh instruction o'er the mind." All are agreed that educational method throughout the curriculum would require a great increase of teaching staff and, as Professor McMurray mildly puts it, "an alteration of the outlook of at least some of the teachers." Others would add, "of the examiners too." There is naturally some rejoicing that adequate payment of clinicians will free more and more of them to follow their bent from one school to another, from university to university; that inbreeding amongst clinical staffs will therefore become less prevalent; and that if and when classes are small enough there will really be time and space for educational method.

There is a strong feeling for the seminar or class where student and teacher exchange ideas, for student as teacher

of student, or even for such a pronouncement as Trousseau used to make to his class at the commencement of a term, "I expect to learn as much from you as you from me." All teachers are concerned to cultivate the "scientific method" and to exercise it by example and experimental practice until, like the aseptic ritual of the surgeon, it becomes a habit that cannot be broken. At the back of their minds is the fundamental distinction between teaching and education, and a feeling that in the use of the collective-study method there is an immediately practical way whereby the student may educate himself and from the first day of his entry feel the implications of the last of his pupilage.

Professor Pickering, as might be expected, claims for physiology a foremost place as an educational tool; he, like many another, would see clinical medicine not only based upon, but indissolubly permeated with, physiology. He would so far as possible use man, and that man often a fellow student, as the experimental animal. Others insist on focusing the phases of study on one ultimate intention, each teacher abstracting from the great excess of material at his disposal that illustrative part, and that part alone, which will arrest the attention of a student intent on his objective of caring for the sick—and this the more easily now that function can be described in terms of molecular shape. All the basic sciences and many clinical problems are concentrating to-day on the molecule as their ultimate target and have at service, in the tagged atom, a research tool of great value.

With agreement on the importance of educating the medical neophyte in scientific method there appears again and again the plea for a humane and humanistic approach, an indication of awareness that by concentrating on the science and despising the art of medicine it would be quite possible to throw the baby out with the bath-water. Professor Arnott, in his carefully thought-out paper in our opening pages, asserts that "Science is disgraced by the over-zealous application of elaborate technical investigation, regardless of the patient's emotional state." Some at least are on guard lest too much trust in measurements, fallible and delusive as they may easily be in inexpert or lazy hands, should overwhelm the humanity of the doctor in his comprehension of his patient. "The training in scientific method, whilst providing the student with capacity for logical, impersonal, objective thought, should add point both to the skill with which he applies his treatment and to the understanding and fellow-feeling that soften his conversation with his patients."

Thus, though psychology has made but a shy appearance in these articles, it lurks in every corner, and the 'prevailing emotional pattern of man" seems unlikely to be entirely overlooked. That is as well, for, as Professor Crew points out, an additional duty is now imposed on those who educate the medical student: besides teaching him the methods of his trade, they must instil into his mind and character the culture that once was the peculiar and exclusive prerogative of the humanities. A prospective student who reads these articles, if he becomes aware that the curriculum prepared for him is in many ways defective, will nevertheless be convinced that his interests are the subject of great concern to his future teachers and that his own endeavours will have a fair field and no impediments.

A situation that demands precise and unshrinking consideration must be faced. The national finances are in so precarious a state that thought must be devoted to what share of the country's total income can be afforded for the promotion of health and the treatment of sickness. The decision, while not disregarding the dictates of civilized human sympathy, must be dispassionate and realistic. This is a matter of national policy. So far as the medical profession is concerned, whatever material economies may be made, however much "overheads" may be cut on the hospital account, and however distressing it may be to postpone the day of palatial health centres, it is clearly a duty so to educate the generality of medical men that far from declining into little more than "medical orderlies"—of which there is a real danger—they should, on the contrary, apply their trained intelligence so that their individual service may be effectively spread over the whole field of prevention, social well-being, curative method, and restoration to productive citizenship. Education in and by the scientific method certainly; but that method must extend into realms where exact experiment is difficult, where there are factors that cannot be singly eliminated, and where emotion is imponderable but dominant.

SURFEIT OF DIPLOMAS

All plans for the reform of medical education are to some extent held up by the natural inertia of those in control of the medical curriculum at the teaching hospitals. There is not in medical education the same scope for initiative and experiment as there is in general education. And all schemes of reform sooner or later come up against the formidable obstacle of the examination. Many earnest words have been written on the value of a sound general education to the youth who intends to be a doctor. Much more might be said of the need for a good all-round education in general medicine, especially for those who intend to be specialists. The time may yet come when all who qualify will have to spend some time in general practice before being allowed to specialize. In the meanwhile the drift to specialism continues, and the young doctor who seeks to

avoid the most arduous medical life—general practice—finds before him a tempting array of special diplomas, acquisition of any one of which will enable him to stake his claim as a specialist.

The Conjoint Board now offers ten special diplomas, eight of which were in existence before the war; the diplomas of physical medicine and of industrial health have since been added. Since 1938 thirteen provincial universities in Britain have made provision for taking the D.P.H., a diploma, incidentally, for which there is more justification than for many of the others. Nevertheless the issue of diplomas on a wide scale to accommodate the different divisions of medical practice illustrates the tendency to the atomization of medicine. If this tendency continues medical men will cease to be "doctors," men more or less learned, and instead become mere technicians able to tinker with local parts of the human machine. The unfortunate patient, with no one to see him as a whole person, will pass along a conveyer belt to be assembled, perhaps, by an administrator in a central records office.

It is worth noting that in recent years those homes of real learning, Oxford and Cambridge, have offered only one special diploma each. The worst offenders are the Royal Colleges of Physicians and of Surgeons through their Conjoint Board. There is, of course, a financial side to the issue of diplomas, and the Colleges may be naturally apprehensive of their financial position if, for example, the Conjoint qualification, M.R.C.S. and L.R.C.P., is abolished, as was implied in the Goodenough Report. But finance must not be allowed to dictate the policy of medical education, nor would one suggest that it does. The mushroom growth of diplomas is no doubt in large measure due to demand. And such a demand is in itself a reflection upon the inadequacy of medical education. The foreign doctor, it has been said, looks with amazement and mockery upon the alphabetical beads the British doctor can string after his name.

If we may assume that a specialist will confine himself either to a part of surgery, or to a part of medicine, or to the combination of the two in obstetrics and gynaecology, there would seem to be a rational way out of the diploma maze. Just as no one is allowed to qualify until he has been grounded in the whole of medicine, so, surely, no one should be allowed to specialize, say, as an otolaryngologist until he has proved his general competence as a surgeon. The F.R.C.S. of England is the hallmark of this general competence, and no additional diplomas should be needed to indicate that the F.R.C.S. is competent to practise as an otolaryngologist, ophthalmological surgeon, thoracic surgeon, or what else. His special competence is recognized by his appointment to special hospitals, or departments of general hospitals, and by his contributions to learned societies and periodicals. The position of the physician is now somewhat ambiguous because of the present policy of the Royal College of Physicians in relation to the M.R.C.P. But until now the passing of the examination for the M.R.C.P. has been taken to indicate general competence to practise as a medical specialist. What need, therefore, to urge the would-be paediatrician to add the letters D.C.H. after his name? Manson and Ross were able to make their discoveries without the assistance of the D.T.M.&H., and Sir Alexander Fleming hit upon penicillin unaided by the D.Bact. now offered by London and Wales. The real danger of the special diplomas is that they will ease the way to special practice for those who cannot pass the test of such general examinations as the F.R.C.S. and the M.R.C.P. This will lead to a lowering of standards and of competence, to the detriment of medicine and of the public medicine serves. A strong case could be made out for retaining such diplomas as the D.P.H. and the D.P.M. The medical officer of health applies his art and science in a way quite different from that of the physician or surgeon. He deals with the collectivity and not with the individual. Some mark of his special competence would seem to be necessary. And with the present division between "mental" and "physical" medicine the practice of psychiatry, too, must largely be in the hands of those whose special training is proved by the possession of a diploma.

Now that the National Health Service has been launched the whole question of consultant and specialist practice should be reviewed, perhaps by a special commission of men and women representative of the teaching centres of Britain. An inquiry into the qualifications of consultants and specialists is urgently needed, and a long-term policy should be laid down if the medical profession is not to drift into the position of accepting the second best offered by endless permutations and combinations of all the letters of the alphabet.

PROSPECTS IN THE N.H.S.

"It must be brought home to boys and girls, to their parents and school teachers, that there is no profession offering a wider range of interests than Medicine, and that children of ability need not be deterred from entering the profession through lack of money." The Goodenough Report,[1] from which this passage is quoted, was published in 1944. Have the events of the intervening five years made any difference to the prospect before the medical student and the newly qualified doctor? The present is a difficult time to answer this question, for the manner in which the National Health Service

will develop cannot yet be foreseen, and the period of transition which began on July 5, 1948, is likely to last for a long time. At the medical schools also the last few years have been exceptional because of the effects of the war and of compulsory service in the Forces.

In one direction a great change has already come about. A student who passes the stiff hurdle of entrance into a university can now more easily obtain financial help, if he needs it, than ten years ago. Even parents who may be considered relatively well off are finding the burden of paying for the medical education of their children increasingly heavy, and it seems certain that as time goes on more and more medical students will receive financial assistance from the State and from local education authorities. A university or college scholarship will continue to be a distinction for exceptional ability. Early in 1948 the Minister of Education, replying to a question in the House of Commons, stated that the Ministry was making at that time 2,540 grants to medical students[2]; no figures were available to show the number of similar grants given by local education authorities. Parents of a boy or girl who has succeeded in entering a medical school and who can show that the cost of the medical education of their child would be a crippling expense should apply to their local education authority for information about the grants available.

What of the prospect before the newly qualified doctor? Certainly the salaries of junior posts in the hospital service are better than they used to be. Furhermore, entry into the superannuation scheme dates om the time of taking up the first appointment. Every encouragement should be given to the young doctor to widen his experience in hospital after qualification, and doubtless it will not be long before one of the conditions of registration will be, in the words of the Goodenough Report, "a compulsory period of approved and responsible clinical practice under supervision." In *The Training of a Doctor* the Medical Curriculum Committee of the British Medical Association discussed "the intern year" at some length and made many sensible suggestions about how the work of the "interns" should be arranged.[3] There is still keen competition for house appointments in teaching hospitals, but the newly qualified doctor who fails to "get on the house" may stand a good chance of obtaining an appointment at one of the satellite hospitals associated with his teaching school, and he will be able thereby to keep in touch with experienced teachers during this important stage in his career. It is when he has finished his junior house appointments that the young doctor is faced with a number of difficult decisions. If he has decided to go into general practice or into one of the Services—including the public health and colonial medical services—he can make his plans accordingly, but if he wishes to specialize or to remain in the hospital service he would be wise to consider carefully what his chances are of reaching the position which he desires. During the past 30 years young doctors have been increasingly attracted to specialist work. If anything the N.H.S. increases the attraction, and competition will be keener than ever.

The way to a specialist appointment is ordinarily through the grade of registrar. It is not essential for a registrar to hold a higher degree, but at some hospitals the chances of candidates without the M.R.C.P. for medical and the F.R.C.S. for surgical appointments would be very poor. The pressure on the aspiring specialist to take one or more of a "surfeit of diplomas" is also increasing. It is, as it used to be, the step from registrar to specialist that is the most difficult. It was not uncommon for the man or woman who wished to obtain an appointment on the staff of a non-teaching hospital to go into practice in the area served by the hospital and wait for a vacancy. An established local practitioner with the necessary hospital experience and qualifications stood a good chance of securing the desired advancement. The more impersonal method of selection in the National Health Service has raised doubts whether he is now so likely to succeed. Many registrars are at present gloomy about their prospects, but there is hope in the fact that the hospital service is far from the stage of full development. In the debate on the Second Reading of the National Health Service (Amendment) Bill, Mr. F. Messer, the chairman of the Central Health Services Council, said about the hospital service: "We cannot look for contraction; there must be expansion." He added that there were areas in the country in which the hospital service was inadequate, and that in these areas there will be a need for more specialists.[4]

For the doctor who wishes to enter general practice things are easier in one respect than they used to be and harder in another. He can, of course, enter practice by putting up his plate in any open area with the permission of the Medical Practices Committee. For those who prefer the more usual approach to general practice no capital has to be found nowadays for the purchase of a practice in the N.H.S. (though the purchase of a house may mean heavy expenditure), but the doctor who wants to obtain a practice must submit a formal application for an advertised vacancy. The number of applications to fill these vacancies is large at the present time, especially when the practice is in an area which is popular with doctors. Another difficulty for the man or woman seeking to set up in practice lies in the fact that certain areas of the country are "closed," the Medical Practices Committee having decided that the number of doctors undertaking to provide general medical services in them is

for the time being adequate.[3] A doctor usually takes an assistantship if he wishes to enter general practice, and this is probably the best way of being introduced to it, especially if he becomes a trainee assistant under the guidance of a principal selected to train entrants to general practice. Many principals seek an assistant with the intention of offering a partnership if the assistant proves his worth. During the next few years the distribution of general practitioners throughout the country will be changing, and it may be some time before the new machinery works smoothly. Practitioners who require advice about the method of entry into general practice should make use of the Medical Practices Advisory Bureau, which the British Medical Association set up at the end of last year; one of its functions is to introduce partners, assistants, and locums. The Bureau, which maintains an information service about openings in the various fields of medical practice, may also be able to give helpful advice to specialists and others seeking appointments outside general practice.

TRAINING IN PUBLIC HEALTH

The scope of preventive medicine is being constantly enlarged. No single practitioner can now be expert in the whole subject, and some degree of specialization has become essential. At one time, for example, the health officer was expected to have a detailed knowledge of the young science of bacteriology; but such great advances have now been made along this road that even bacteriology applied to hygiene is itself a lifelong study. The practice of public health in the field is also limited by political considerations, and teaching should take note of changes brought about in this way. From the beginning of the present century—to choose a simple illustration—preventive medicine has become more and more closely linked with personal health. In the meantime many of the environmental services have become so highly developed technically that they have been rightly handed over to the architect and the sanitary engineer. The medical officer of health gladly shouldered the burden of maternal and child care, and played a notable part in the evolution of the statutory schemes for the prevention and treatment of tuberculosis, venereal disease, crippling conditions, and other social handicaps of great importance to the nation. These services were built up in a comparatively short time to a remarkable state of efficiency.

In the year 1929 a large number of hospitals came under the direct administration of the medical officer of health, and in the course of the next ten years many of them were transformed from typical "poor law institutions" to progressive modern hospitals. They stand to-day as monuments of wise local government and excellent teamwork among the officers of local authorities. Nevertheless hospital administration was apt to take precedence over the proper functions of the medical officer of health. He has no reason to deplore the recent restoration of hospital and other remedial services to the fold of clinical medicine, for he should now have time and opportunity to concentrate on his own job.

Postgraduate teaching in public health was slow to follow these progressive changes. In the past, it has to be admitted, the study of the personal health services was only sporadically introduced into the course, while the intricacies of bacteriology and chemistry still received too great a share of the student's attention and loomed too large in the examination for the D.P.H. At the end of the last war, however, a new syllabus came into operation. It was intended to cover an interim period "while the new medical services are taking shape." The nine months' course for the full D.P.H. was retained, but the first three months were to be devoted to a general review of the health services. A Certificate in Public Health was given to those who passed an examination at the end of this period of study. It was believed that a large number of students, content with the certificate, would then proceed to advanced clinical work in paediatrics, tuberculosis, and the like. In fact nearly all the students go on to take the full course for the diploma in public health.

This interim curriculum is already out of date, and the courses for the diploma are being adapted to keep pace with the times. In particular, more attention is being paid to practical social work, to industrial health problems, and to the vast field of epidemiology. Elective subjects are taking their place in the curriculum here as in the United States, and stress is laid on the day-to-day observations made by the student in his notebook. Public health is not only not in decay: it has not nearly reached maturity. As Sir Farquhar Buzzard said in a Harveian Oration eight years ago: "It exhibits precocities of growth and promise of further development. It has already accomplished much in its fight against slums, dirt, infection, and industrial disease. It has done much indeed for the health of mothers and children. In short, the history of our public health services is one of which our country may be justly proud."[1]

It is necessary to think well ahead if the framework for the new public health service is to be soundly constructed. If the present course for the Certificate in Public Health were to be given in the undergraduate years it should be easier for the general practitioner and the health officer to work more closely together to promote health of mind and body. This task has always

[1] *Lancet*, 1942, 1, 343.
[2] *British Medical Journal*, 1949, 2, 326.

been hard, and it is not likely to be made easier in the near future. For one thing the Government, preoccupied with working a statute which is mainly concerned with the sick, is busy with remedial care; for another, the medical practitioner, as yet untutored in prevention, is consulted only when people are ill. The local health authorities are still smarting under the blow which tore from them the hospitals in which they took so much pride. And the multitude care little about health so long as they are reasonably well.

The health officer's special responsibility is to safeguard the health and well-being of the community he serves. Now that he has been relieved of his clinical burdens he can give his full attention to the study of health and of the foundations of disorder—epidemiology in its broadest sense. In this territory he should once again be a pioneer. Further, the medical officer of health has a clear duty to translate the technicalities of science applied to hygiene into terms which the public can understand. The basis of local government in this country is the presentation of expert knowledge in such a way that the layman can grip it and act upon it. The M.O.H. is an interpreter. If these principles are right, then the course for the D.P.H. should be educational rather than narrowly vocational. On the one hand it should give the student an understanding of how the sciences can be applied to the practice of health, and on the other it must afford abundant opportunity for him to grasp the social functions of medicine—the study of man in relation to his home and his family, his work and his play.

The prospects of a career in public health have never been better. The work is interesting, and there is wide scope for experiment and imagination. The ties of office work have mercifully been lo[illegible]ened since the National Health Service Act came into operation. Financially the rewards of a career in public health will always be less than clinical medicine can offer, but it is encouraging that the dispute between the British Medi[illegible] year [illegible] Associations and the local authority associations at some length gestions about how the wo[illegible] of public health medical officers arrang[illegible] and [illegible]re is still ago.[2] The representatives of t[illegible] the remuneration ow agreed to take part in the settled a few weeks ching ho[illegible]nctional council under the local authorities have into "get tors in the public health rmation of a medical fu[illegible]ining f knowing that their case Whitley machinery, and doc[illegible] assoc[illegible]ust now be heard. service have the satisfaction o[illegible] th[illegible] for improved scales of salary r[illegible]

TEACHING OF MEDICAL BACTERIOLOGY

[illegible] bject which can easily [illegible]dent must know how bacteriology is not a [illegible]dy defends itself against The medi[illegible] overcome this defence, how they cause, and how death or recovery takes place. For practical reasons he must be taught what specimens to take, how and when to take them, and the information to send to the laboratory with them. He must also be familiar with skin tests in common use to indicate infection or susceptibility and know what preparations are used for prevention and treatment. The student's understanding of future developments in the diagnosis, prevention, and treatment of bacterial disease will depend on his knowledge of the nature of bacteria and, in particular, their metabolic processes, for it is interference with these which seems to offer greatest hope for the control of infectious disease.

One of the problems of the teacher of medical bacteriology is to give a balanced review of the subject in all its aspects within the limited time allowed in the medical curriculum, and in this connexion Professor R. Cruickshank[1] has recently made some constructive suggestions. He very rightly maintains that bacteriology should not be taught in isolation, but should be integrated with other subjects, particularly with pathology, epidemiology, and clinical medicine and surgery. Demonstrations, tutorials to small groups, and bacteriological clerkships all have great educational value. Professor Cruickshank believes that the teaching of bacteriology should be in four stages: during the biology course; in an introductory course in general pathology; in an intensive course in pathology and bacteriology to be taken after at least one year of clinical work; and during bacteriological clerkships in the final year. Such a scheme obviously has great advantages, but some medical schools may find it requires too much time.

The proposal that instruction in the principles of bacteriology should be given during the biology course is valuable. If included towards the end of that course the subject would catch the student's interest as something obviously related to his future work. There might, however, be a danger of reducing the load in one course by overloading another. The inclusion of bacteriology in an introductory course in general pathology puts the subject in its proper perspective for a medical student as a branch of pathology. Another object of the introductory course is to bridge the transition from "the familiar and normal to the unfamiliar and abnormal." At this stage the approach should be from bacterium (much about the bacterium) to patient (only a little about the patient). When the student is ready to cross the bridge his teacher should cross it with him by leaving the class-room and going into the ward. The approach would then be from patient to bacterium. Students, under supervision at first, would study the patient, consider what, if any, bacterial cause there might be for his illness, take the appropriate specimens, and either follow or themselves carry out the examination in the laboratory. Finally, there would be discussion with clinician and pathologist of modes of infection, pathological changes, treatment, and prevention.

Such a method of teaching small groups of students would give a balanced view of bacteriology and integrate it with other subjects. Many teaching hospitals have a number of bacteriologists on their staff, and all should be called on for teaching; but it might be more difficult to find suitable teaching laboratories. After this period of work under supervision the student should be able and be

required to work on his own. During his medical clerking he should be expected himself to take and examine specimens from his patients. Only by accepting responsibility will he really learn.

TEACHING OF TROPICAL MEDICINE

At the present time there are three centres in this country at which postgraduate courses of instruction in tropical medicine are given: these are in London, Liverpool, and Edinburgh. The length of the courses is about five months, and the students then sit an examination for a diploma in tropical medicine and hygiene. That in London is conducted by the Conjoint Board, and those in the other centres by the universities concerned. Their original purpose was to fit medical men for clinical practice in the Tropics, essentially to familiarize them with a variety of diseases of which they learn little or nothing in the ordinary qualifying medical curriculum in this country. Among the diseases which are of more peculiarly tropical distribution those due to protozoa, to spirochaetes, and to helminths are of very great importance. The study of these cannot be confined to the more rigidly clinical aspects of their diagnosis and treatment; it entails an introduction to subjects largely foreign to the graduate in medicine in this country. It is impossible to understand the parasitic diseases of man without a sound knowledge of the parasites causing them and of the vectors which convey these parasites. The student's course of study must therefore include clinical parasitology and medical entomology and zoology in order to give him sufficient knowledge to undertake ordinary tropical practice. The basic requirements of the curriculum are thus wide, and not least of the difficulties for the student is the acquirement of an extensive new vocabulary.

Learning the facts about tropical diseases is largely valueless in medical practice without skill in the technical examinations which are necessary for diagnosis and for the control of treatment. The help of a laboratory, so easy to obtain in this country, is but rarely available in the Tropics, and the medical practitioner there must be his own clinical laboratory technician. To give him confidence in his ability to do this work a large proportion of his time in training must be spent in the laboratory if he is to acquire the necessary technical proficiency. The need for this is great, for teachers have found that many postgraduate students coming for training cannot even use a microscope competently. In addition to essential instruction in tropical diseases the three courses now include a wide range of subjects such as ethnology, nutrition, sanitary engineering, field surveying, public health practice, epidemiology, and vital statistics. That adequate knowledge of each of these can be acquired by the student in so limited a period is doubtful, and in the attempt to absorb it there is a very real danger that the facts necessary for the ordinary practice of his profession may be obscured.

Restriction of a curriculum to assimilable proportions without omission of essentials is a problem common to all branches of medical education. In this case the primary object is to equip the medical graduate for his immediate duty as a general practitioner in the Tropics, and a preliminary course of study might well be limited to this. After experience in the Tropics the practitioner would have first-hand knowledge of the medical problems of his own district, and he would know which were capable of solution by his own efforts. Armed with this knowledge, he would be in a far better position to seek and to assimilate a wider range of information to this end. Those who advocate a preliminary course of instruction in tropical medicine of rigidly limited scope and of severely practical aspect have a strong case. At a later date medical officers with practical experience in the field could take a more advanced course of study. The preliminary course might be followed by an examination, which would in effect afford a certificate of competence to practise medicine in the Tropics. The advanced course would be much less stereotyped and could be varied to meet the needs of individuals; an examination after this course might be dispensed with.

THE B.M.S.A.

Though the British Medical Students Association has to contend with the problem of all student bodies in that after a short time medical students—or most of them—become doctors, it continues to flourish and to increase its activities. It confines its work to studying and trying to fulfil the needs of medical students as medical students and eschews political controversy and other ulterior affairs. Its wholly laudable aim is to increase co-operation between medical students themselves as well as between them and the medical profession, students of other faculties, and students overseas. Several times a year it holds clinical conferences at various centres, where authorities on different aspects of medicine give lectures and demonstrations, and three times a year it publishes an excellent journal. *The British Medical Students Journal*, which is edited by students and has a circulation of over 4,000, contains articles both on clinical medicine and on its historical and cultural aspects. Last year the association also published a diary for 1949—an enterprise that will be continued each year—which includes many pages of tabulated clinical and pharmacological information. It is a useful pocket-book for the medical student, though he might be wiser to leave it outside the examination hall with his textbooks.

The association's annual general meeting, which is to be held at Edinburgh on Nov. 11–13, is attended by representatives of the constituent bodies. These are the great majority of the medical schools in Britain and Northern Ireland. As a result of decisions taken at last year's meeting the association inquired into billeting fees paid by students taking their midwifery course. They were found to vary from £1 to £3 a week, and it was suggested to the Minister of Health that they should be a charge on the Hospital Service. He did not agree, and contended that it was a question for the medical school or university. Another problem investigated—and this time with greater success—was the ex-Serviceman's grant. A meeting was held with the Ministry of Education, and certain anomalies were adjusted. The B.M.S.A. is playing a useful role in investigating students' problems and advocating solutions to them. It deserves the backing of all medical students, for no case, however good, can succeed unless it is well supported by the evidence and effort of the majority of those concerned.

THE TRAINING OF THE TEACHER

BY

W. R. NIBLETT, B.A., B.Litt.
Professor of Education in the University of Leeds

At least fifteen thousand teachers are sent newly trained into the schools of the nation every year. Most of them are trained in colleges which offer a two-year course, but teachers who take up posts in secondary grammar schools and an increasing number of those joining the staffs of other types of secondary school are graduates who have had in all a four-year period of training—the first three years being spent at a university in reading for the degree of B.A. or B.Sc. and the year after graduation in a university education department.

During his three years' course the undergraduate will have been fully occupied in his academic studies and will have concentrated upon securing the best degree he can in the subject or subjects of his choice. The postgraduate year of training is therefore a year during which his mind and personality have to be acclimatized to the idea of teaching. It may have been some years since he has even been inside a school, and he is not likely to be very well aware of his own capacity or deficiencies as a teacher of boys or girls.

But the task of a university education department is much wider than that of giving a student various hints and tips about the techniques of teaching in the classroom and of providing chances of practical experience of such teaching. It is true that the total length of the course is quite short. It amounts to about thirty weeks in all, perhaps seventeen of them spent in lectures, discussions, and classes at the university and the remainder in "teaching practice" in schools of various types. In these thirty weeks the student has to be introduced to some of the social, philosophic, and psychological bases of education. All university education departments are anxious that students should not think of the job of teaching simply as one of instructing John and Mary in a particular subject or subjects. The education which a nation gives to its children is an intimate expression of its social and national purpose and character: the children of a nation *are* its future. It is not merely what they are consciously taught in schools that will matter but the unconscious presuppositions and values which the school as a society will impart to them.

A very important element in the training given to the teacher is his study of the psychological development of children. Such instruction as he receives on the psychology of childhood is no substitute, of course, for personal understanding of children as human beings. But some knowledge of human psychology can undoubtedly deepen understanding of child behaviour and mental growth. A certain number of lectures are given to students upon the physical development of childhood and upon principles of health. There may be lectures, also, upon the history of education in this country, contemporary educational developments in other nations, and the general administration of education

All the lecturers in an education department are themselves teachers of experience, and students take part with them in discussions on teaching methods. During the year the students have experience of trying to teach boys and girls of various ages. This gives them a chance of learning how to co-operate with themselves as teachers, how to shape lessons of many sorts, how to make effective contacts with children of differing temperaments and abilities. During their periods of practice they are encouraged to look upon teaching as an art and a craft calling for great demands not merely upon their knowledge of a subject but upon their human understanding and their skill in interesting an audience and helping it to learn.

Social Factors in Learning

Clearly there is much in common between the training of a doctor to be a good doctor and a teacher to be a good teacher. It is significant that in these days there should be an increasing emphasis in teacher training upon the importance of social factors in learning, just as there is an increasing emphasis upon social factors in medicine. Similarly, it is realized more and more that the individual child cannot be understood simply as an individual. He must be seen as intimately influenced by the family in which he has been brought up, the social class to which he belongs, his environment of street and newspaper and public opinion. Educational psychology is to be seen as a branch of social psychology. The time allowed for discussions in small groups between students and their lecturers has its counterpart in the case of students training to be doctors.

The training of the teacher, whether in a two-year training college or in a university education department, is not of course to be thought of only as a narrowly professional business. If the student is to make a good teacher he must during the whole time of his training be enriching his humanity. It is important that his capacity for experience should be increased as well as his knowledge of education as a subject and his skill as a practitioner. The experience of students can be stretched in many ways, and use can be made of the arts, the novel, the film, and also of travel. It is important that students training to be teachers should not merely read textbooks upon child development or methods of teaching, but stories about childhood and the childhood parts of various autobiographies. It is very enlightening to them also to read something about education in primitive societies. Such absorbing studies of life in primitive societies as Margaret Mead's *Growing Up in New Guinea* or *Coming of Age in Samoa* are valuable books upon education itself.

Institutes of Education

Since the war, great developments have been taking place in the organization of teacher training in this country. The country has been divided up into regions, each with an institute of education centred upon a university. Henceforward these institutes will be responsible for the training given to teachers within their area. This will inevitably bring about the gradual development of much closer relationships between the two-year training colleges (which in due course will offer three-year courses instead of two-year) and the universities themselves. The Ministry of Education will in future recognize as qualified teachers only students who have secured a qualification awarded by one or other of the institutes of education.

But institutes, like medical schools, are not concerned only with the initial training of teachers. A very important part of their work will be in "postgraduate" education—in the continued training and education of teachers already in the field. In the past there have been, of course, summer schools, refresher courses, and evening lectures for teachers who cared to attend them. With the coming of institutes of education, however, the scope and provision of such methods of continued training will be much enlarged.

Post-certificate qualifications for trained teachers are likely to come into existence in considerable numbers. Thus a graduate who has had an initial year of teacher training immediately after receiving his first degree will be able to add to his qualifications as a teacher by taking a more advanced diploma after having taught for some years. This may be general in character or of a specialized sort—e.g., a diploma in primary education, or religious education, or the administration of education. Corresponding qualifications will also be open to those who have qualified as teachers after a period at a two-year training college.

Educational Research

A third concern of an institute of education is with the organization and encouragement of educational research. Here again there is a parallel with the centres of medical education. In all the five main fields of educational investigation vast territories remain to be discovered—in the sociological, psychological, historical, comparative, and methodological fields. Educational research is not to be regarded simply as a matter of discovering more about actual methods of teaching in the classroom or about more efficient means of examining children at various stages in their school career. We need to know much more than we do about, for example, the educative influence of the cinema, the adaptation of the school curriculum to fit contemporary needs more effectively, the influence of classroom and school design upon the education given within the buildings which have been put up. The curriculum itself in most types of school is what it is for traditional rather than really educational reasons.

Most institutes of education are building up libraries of books available for loan to teachers in their area. They have already begun to publish accounts of experiments and researches which are taking place under their auspices. Indeed, an institute which is really awake will be seeking out and encouraging all sorts of investigations, projects, and new methods within the schools and colleges of its area. It will act as a focus and fertilizing place for vital ideas on many educational matters.

There is an obvious parallel between the work of university institutes of education as they are developing and medical schools which specialize in postgraduate education and advanced medical research. It may be, however, that in institutes of education continued teacher education and the findings of educational research are brought into closer relationship with one another than is sometimes the case in medicine. As time goes on the need is likely to become more apparent for a closer linkage between institutes of education and the departments of medical schools concerned with child health, mental health, and social medicine generally. The doctor in training and the teacher in training have much to give to one another, and so have the staffs engaged in training them.

The Central Council for Health Education held a summer school at the School of Domestic Economy, Eastbourne, from July 28 to August 11 under the direction of the Council's Medical Adviser and Secretary, Dr. Robert Sutherland. This year not only the subjects but the method of study were of interest to both pupils and tutors. The subjects were "The Nature and Needs of Man" and "The Contents, Principles, and Practice of Health Education," and the method of study was that of tutorial group discussion. A short consideration of the theory and method of group discussion completed the course, which was supplemented by the showing of films and a display of health education material and books. The students were drawn from all fields where health education is of importance.

NURSE-TRAINING AND LEGISLATION

RETROSPECT AND PROSPECT

[FROM A SPECIAL CORRESPONDENT]

When the Nurses' Registration Act was passed in 1919 after long struggles and much controversy it was assumed that the field had been won. The goal on which the nurses had set their hearts was the formal recognition of nursing as a profession. This implied a recognized qualification, and the qualification had been found in State registration. Since that time nurse-training has become more and more a process of obtaining the greatest possible number of passes in the State examinations. Efforts to help other countries to bring their nursing to a higher level have generally included the imposition of a State diploma and of minimum requirements not unlike ours—e.g., a three-year training course. Clichés such as "the one portal of entry," "raising the standard of the profession," "professional self-government of nurses by nurses," have largely dominated the thinking of nurses and have raised a barricade against help which might have come from outside.

Is it possible that the paradoxical situation which exists to-day, when in spite of the steadily mounting numbers of student nurses and pupil midwives entering the training schools since 1938 a grave shortage of nurses and midwives for the hospitals still persists, is due in some measure to a too rigid allegiance to the principle of State registration? To approach the question from another aspect, would anyone claim that the essential art of nursing has made any appreciable progress in the last twenty or thirty years? Has there been any real research into nursing skills, nursing practices—one is tempted to add nursing superstitions? Discounting the effects of modern equipment, modern methods of heating, etc., can the patient entering hospital to-day be sure that the nurses will know better how to ensure his comfort and the well-being of his mind and body than they would have done twenty years ago? The delicate and elusive art of making the patient comfortable is the very heart and essence of nursing—without it there is no value in all the talk of "raising standards." It may be that some of the "wastage" and restlessness so evident among young nurses is due to frustration—they were groping towards this ideal when they entered hospital and they have found their days ruled by a flurry of ward routines and by the cramming of indigestible "theory" related to the State examination syllabus rather than to the work they are doing in the wards.

The purpose of these notes is to suggest that the maintenance of State registration in its present form has in fact hampered the evolution of nurse-training rather than assisted it. To trace the processes at work we must look further back than the Nurses' Registration Act of 1919, and further afield than the nursing profession.

The Evolution of Nurse-training

When Miss Nightingale founded a training school for nurses in 1860 with the fund raised in her honour by a grateful nation she sowed the seed for the cultivation of nurse-training schools. Other fine training schools sprang up and made a great name for themselves, but there was one difference—none had the separate endowment and financial independence of the hospital which the Nightingale School had. From 1860 to 1948 the nation made no grants for the training of its nurses. The nurses themselves have largely financed their training by the services they have rendered to the hospitals. It has long been recognized in the hospital

world that the most practical and economical way to staff a hospital is to set up a training school and attract a large body of student nurses—totally disproportionate, very often, to the number of trained staff employed. Even the General Nursing Council, which administers the Nurses Acts, is financed by the examination and registration fees of nurses, so much have nurses been willing to give for "self-government."

When we look at other professions and the means whereby their practitioners are trained we see a different scale of values. Other great liberal professions have not accepted or imposed one uniform national examination and qualification—imagination shrinks from contemplating the results if this had happened in teaching, for instance. Universities and training colleges have been free, have been given the strongest encouragement, to develop their own individual and characteristic courses, and it has been taken for granted that the State should help to finance them, to the tune of many thousands of pounds a year. Moreover, this State aid is not given in order that the graduate may serve the State in a particular capacity.

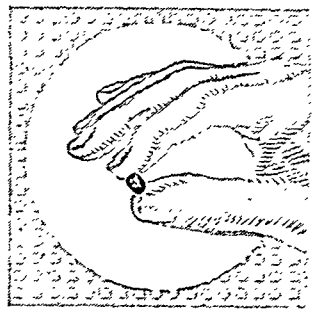
A comparison of the working of the two systems may explain some of the differences in the results.

At the time when the Nurses' Registration Act was passed a number of hospitals were able to award a training certificate which was recognized as the mark of a well-trained and skilled nurse. Other hospitals, though not so famous for their nursing, were able to attract enough "probationers" for their training courses, which varied a good deal in value. For some years the leading training schools still regarded their own training certificate as the true test of a nurse's ability, and in some cases the standard was higher than that required for the State examinations. As time went on, however, policy dictated that nurses should be prepared for the State examinations, and few hospitals, if any, can spare their nurses time now to adventure widely outside the confines of the State syllabus. This has led to an artificial levelling down as compared with the heights which might have been achieved. At the other end of the scale more and more hospitals came to see that their only hope of attracting that economical and manageable unit of labour, the "probationer," lay in opening a training school and offering the training course required for the State examinations. Then it was found that the hospital would have to spend money on class-rooms, teaching equipment, and staff, and there was much counting of the cost, because the money spent in this way must show a good return to the hospital in labour and in the recruitment of more and more probationers. It was, in fact, mere outlay on "maintenance." Class-rooms were improvised in basements, in odd outbuildings; administrative needs dictated that so far as possible the nurses should attend lectures and study in their off-duty time, so that the wards were not deprived of their services. These hospitals could not set a high educational standard for entrance if their staff needs were to be met, and so a system of artificial cramming and parrot-learning was needed, and this did indeed have astonishing results in the unlikely material it forced over the hurdle of the State examinations. Little time was left for that intelligent consideration and understanding of the actual conditions met in the wards which even the "practical nurse" should have.

Once a hospital had gained approval as a training school it was left in peace. It might economize by employing an unqualified sister-tutor and requiring her to undertake also the duties of assistant matron or home sister. Many were the complaints about insufficient teaching, though it must take a good deal of provocation to make a young girl whose energies are already fully employed in the wards rebel on this score. State-registered nurses were found to have had serious gaps and omissions in their experience, and to have spent a totally disproportionate amount of their training time in some ward or department where their experience was of use—all because of the labour needs of the hospital.

Drawbacks of the Present System

In recent years the General Nursing Council has tried to effect reforms by appointing inspectors of training schools, by refusing approval to small hospitals not offering adequate experience, by attempting to impose a uniform educational test for entrance to all hospitals, no matter what the level of their teaching, and by making their requirements more stringent in various ways. The real authority behind the Council's requirements, however, is not the power to give help to the training school or to withhold it, but simply to withdraw approval of the training school, which seriously handicaps the hospital in its efforts to obtain the necessary staff.



A large amount of the nursing work of the country has always been undertaken by nurses who have no training certificate. The services of these people were needed in 1919, and the country has continued to rely on them up to the present day. It is typical of the British outlook that, while the "one portal" of State registration was imposed in 1919, the existence of this large body of nurses who would never attain to it, but whose services were needed, was politely ignored until 1943, when the Nurses Act provided for a second national standard—that of the assistant nurse—and for the restricted use of the title "nurse." It is interesting to speculate whether the shortage of the "practical nurse" would be so acute to-day, and the number wishing to be assistant nurses so few, if the existence of and the need for the assistant nurse had been frankly admitted in 1919.

The 1943 Act still further hampers the hospital's efforts to staff nursing staff by restricting it to the State-registered nurses or enrolled assistant nurses (admittedly far too few for present needs) or to those taking a recognized training course. Thus we have the hopeless situation in which the General Nursing Council tells a hospital it can no longer be a training school because it has not enough beds in use. The hospital must then send away the student nurses it has, and, since it is no longer a training school, it cannot hope to find the staff it needs; still less can it open additional beds. Here lies the real tangle of staffing and training—not simply, as some have supposed, that the training course consists of too much ward work and too few lectures.

An Alternative System

It has been suggested above that the power behind the General Nursing Council's influence on "standards" is not the ability to help the hospital to offer a better training course but the threat to withdraw approval and thus to prevent it from recruiting student nurses. What alternative is there? It is taken as quite a natural thing that the University Grants Committee should distribute between £5,000,000 and £6,000,000 annually on behalf of the Treasury in grants to universities and colleges. By their grants, given after periodical visits, the Grants Committee can foster what is best in the educational system of each institution. Where things are amiss they can apply sanctions by refusing grants unless reforms are made, and at the same time make those reforms possible by offering the necessary financial help.

What is needed for nursing is, first, a separation of the finances of the training school from those of the hospital,

Increased Vitamin Potency

THE VITAMIN CONTENT OF CROOKES HALIBUT OIL CAPSULES HAS NOW BEEN INCREASED ALTHOUGH THE PRICE REMAINS UNCHANGED

IT has become possible to increase, by as much as one-third, the vitamin content of Crookes Halibut Oil Capsules. Each capsule now contains 6,000 International Units of vitamin A and 600 International Units of vitamin D. The label on each pack states a guaranteed potency.

CROOKES Halibut Oil Capsules

The world's new weapon against pain

GLAXO HEPTALGIN

Pain therapy took a step forward with the introduction of 'Heptalgin,' a compound evolved and synthesised in Glaxo Laboratories. 'Heptalgin' has an analgesic activity appreciably *greater than that of any of its predecessors in this field, yet it has* a relatively much lower acute toxicity. Apart from mild drowsiness following full dosage, the substance is usually free from hypnotic effects and the patient remains alert during treatment. Moreover, 'Heptalgin' does not cause constipation when administered within the normal range of dosage.

Tablets (*10 mg.*): *In bottles of 25 and 100*
Ampoules (*10 mg. in 1 cc.*) *In boxes of 6 x 1 cc.*

ANDROGENS
in Gynaecology

The rationale for the use of androgens in the female is based on their ability to produce a reflex pituitary inhibition. Androgens may therefore be substituted in certain conditions where œstrogens are contra-indicated or have been tried and found ineffective. The clinical application of androgens in the female includes hypermenorrhœa, whether functional or of menopausal origin, mastodynia, pre-menstrual tension, dysmenorrhœa, frigidity and more recently, the treatment of advanced carcinoma of the breast.

The British Schering range of androgenic preparations includes:

'TESTOVIRON' for parenteral administration; it is an oily solution of testosterone propionate.

'ORAVIRON' for oral and sublingual therapy, which in adequate dosage reproduces all the known effects of parenterally administered androgen.

'TESTOVIRON' Ointment is available for topical application when a local effect only is required.

and, secondly, a body analogous to the University Grants Committee, composed largely but not exclusively of nurses. The Grants Committee would be entrusted with an annual block grant from the Treasury, and would have the power to distribute this money in grants for satisfactory training projects and to withhold it from those training schools which did not offer an adequate course. It would also decide which training schools were worthy of recognition and therefore able to confer a qualification on their graduates, but this would not imply in every case the rigid following of a standard syllabus laid down by an outside body. Just as the teaching profession has a wide range of courses, from that of the training college for primary school teachers to the honours course of a university, so the training schools would be able to adjust their teaching to the capacity and needs of the student body which each was able to enrol.

The efforts of the nurses to establish a university school of nursing indicate a groping in this direction, but the need is not merely for one school here and there distinguished from others by its academic standard, but for freedom for a number of training schools to spend money on their teaching course and to develop that course on the lines which seem best for the students they admit. Schools of this type would preserve the apprenticeship system to which British nursing owes so much, but the fact that the training school was separately financed should ensure that the training course was not sacrificed to meet the varying labour requirements of the hospital.

It may be argued that this leaves too much room for diversity of standards and that the public must have some means for knowing what the term "trained nurse" implies It would be too much to expect every hospital in this country which wished to train nurses to plan and decide its own course of training. These proposals do not rule out the possibility of a national syllabus which the rank and file of hospitals would adopt, with the help of grants from national funds for nursing education and with the stimulus of consultation with the Grants Committee. State registration would be given on satisfactory completion of this course. Its content would be planned to match the ability of the type of candidate on whom the less-sought-after training schools rely—and must continue to rely. It would not presuppose a school certificate standard of education in the student nurses. However much that may be regarded as desirable, it is outside the sphere of practical politics, since the training schools for State registration need an annual intake in the neighbourhood of 20,000 student nurses. But hospitals which could offer something more than the national syllabus would be allowed freedom to develop their training courses on characteristic lines and their training certificate would confer full professional qualification with exemption from the national course.

No lowering of standards is contemplated in these proposals, but rather a fostering of what is best in nurse-training, with the assistance of educational grants, a greater degree of freedom in the presentation of the teaching material to the student body, and a willingness to learn from the experience of older and more seasoned systems of education. Zeal for "standards" and professional status as expressed by State registration has led at times to a levelling down of the best and an artificial levelling up of the poorest. If there were real encouragement and financial support for nurse-training schools to develop on individual lines and to achieve training certificates of their own which would be accepted as the hall-mark of a competent nurse there might be a flowering of the art and science of nursing beyond anything yet envisaged, and with it a raising of the prestige of nursing which would solve much of the present recruitment difficulty.

The Nurses Bill, 1949

The Nurses Bill recently introduced represents a great step forward, inasmuch as it provides a new channel for the finance of nurse-training, quite separate from hospital finance or any other expenditure on the National Health Service. The channel runs from the Treasury through the General Nursing Council and Standing Nurse-Training Committees to the training schools. The Standing Nurse-Training Committees are bodies which may be appointed by the Minister for any region (the Bill does not state that they will be appointed for each region). Their functions would appear to be partly advisory (both to the General Nursing Council and to the training schools) and partly executive, and they are to be staffed by the Regional Boards, though they are not subcommittees of the boards.

The General Nursing Council then becomes the grant-making body (through its Finance Committee) as well as the examining and qualifying body. The question which calls urgently for consideration is whether such an arrangement is likely to secure those elements of diversity and elasticity which are so much needed in nurse-training. Financial independence for the training schools is not enough if they remain tied to rigid uniformity in the curriculum and examinations. Under the Bill, half the members of the reconstituted General Nursing Council are nurses elected by nurses on a regional basis. This method is likely to lead to the appointment of prominent members of the profession who have achieved distinction, possibly as administrators or teachers. It does not seem likely to ensure the special and rare qualities needed to distinguish the potentialities in new and perhaps revolutionary schemes of training, to assess whether their results might be worthy of recognition as at least equivalent to the normal standard for State registration, and to decide how far a training school may be given a free hand and financial independence in carrying out such a scheme. Fundamentally, there would seem to be no objection to vesting the dual powers referred to above in one body if some means can be found of appointing on it the persons best fitted to discharge these exacting duties and to bring vision and sound judgment to the evolution of nurse-training

Remembering that the nurse-training centres number several hundred, in contrast with the small number of centres with which the University Grants Committee deals, it would appear essential to delegate most of the routine assessment of training schools and their needs to the Standing Nurse-Training Committees in the regions, reserving the more "experimental" schemes for the detailed scrutiny of the General Nursing Council. If that were done, the membership of the Regional Committees also would become a matter of great importance. It would not be enough to secure the representation of the various interests in the region. Here again it would be necessary to ensure that each individual sharing these responsibilities possessed the special qualities needed for the work. Present tendencies suggest that salaried appointments rather than voluntary membership of a committee might be called for to secure a sufficient degree of continuity and concentration in the work.

To sum up: while the general outline of the Bill suggests a great step forward, much consideration needs to be given to the constitution of the General Nursing Council and the Standing Nurse-Training Committees, as outlined in the first and second schedules to the Bill, if the objects proposed earlier in these notes are to be achieved.

POSTGRADUATE TRAINING FACILITIES

"In discussions on medical education and duties of medical schools we tend to lose sight of the fact that the best that the student can do in them is to begin to learn. If he does not study much longer and harder after he graduates than he does before he will not become a successful physician."—Dr. J. S. BILLINGS (1851).

Once again we are indebted to Sir Francis Fraser, director of the British Postgraduate Medical Federation, which is a school of the University of London, for up-to-date information. Last year we mentioned the formation of the Joint Board of the Federation and the three Royal Colleges. The Joint Board has met several times during the year and has paid particular attention to the procedure necessary to make available to postgraduate students advice on suitable hospital appointments and programmes of study. Each of the three Royal Colleges arranges courses of lectures in the clinical aspects of their specialties, and the Royal College of Surgeons provides in addition courses of lectures and demonstrations in the basic sciences for potential surgical and dental specialists, and in anaesthetics. Each Royal College provides expert advice and guidance on suitable hospital appointments and programmes of study for its higher qualifications and for other graduates visiting this country for further study, and the services of the staff of the Central Office of the Federation (2, Gordon Square, London, W.C.1) are available to all postgraduates.

Among other recent developments in the postgraduate field is the formation of the Institute of Obstetrics and Gynaecology, which started work in October, 1948, and has lately been inspected by the Senate and recommended for recognition as a federated institute of the University of London. Other institutes which have also been recognized in the same way since last year are those of child health, laryngology and otology, and ophthalmology.

The regional advisers in postgraduate education who were appointed to the four metropolitan regions of the National Health Service at the beginning of the present session have been visiting the hospitals in their regions with a view to ascertaining the educational facilities for specialist and general practitioner training and grading them accordingly. This information is available at the Central Office of the Federation. A start has been made in two of the regions with plans for the interchange of registrars during their more advanced stages of training between the teaching and the other hospitals.

Refresher Courses for General Practitioners

A number of refresher courses for general practitioners have been arranged at non-teaching hospitals in the regions throughout the year. These are open to National Health Service practitioners who receive grants from the Ministry of Health and also to private doctors who wish to attend at their own expense.

As an alternative to the present one-week or two-weeks intensive courses (11-session and 22-session courses), which are not proving as attractive as the Ministry would wish, financial assistance is now available to N.H.S. practitioners for special short courses, consisting of three half-day sessions at the week-end or during the week. The same conditions of grant and procedure apply in respect of such courses, with the modification that a doctor may take a maximum of seven courses of three sessions (or any combination of such courses with the 11-session courses, provided that it does not exceed 22 sessions) in any year. Form G.P.R.C. 2 will be marked by the university or medical school "Special Short Course." The course fee will be paid direct by the Ministry. Travelling expenses and subsistence allowance may be reclaimed by a doctor who qualifies for grant, but it is not expected that any expenses for the payment of a locumtenent will be incurred in these cases.

When the Ministry was asked by the British Medical Association to elaborate this last point, the Ministry replied that as the week-end courses would be held on Saturday afternoons and Sundays it seemed reasonable to expect that there would be no need for a locumtenent. A doctor might not have a Saturday evening surgery, and, even if he had, the times of the session might enable him to carry it through, or it might be possible to cancel the evening surgery and to arrange with a colleague to treat any patients directed to him, as well as to cover any visits which could not be postponed. The same arrangement might cover absences during three mid-week sessions; these might be spread over a period—for example, one afternoon a week.

These short courses (week-end or mid-week) have been introduced on the representation of certain universities, where it is said that they have attracted large numbers of applicants, who at the moment are meeting the entire cost themselves.

London Postgraduate Institutes

Included in the British Postgraduate Medical Federation are the Postgraduate Medical School at Hammersmith Hospital, with its university departments of general medicine, general surgery, and pathology, and a number of institutes in the principal clinical branches of medicine associated with the special hospitals. The institutes are in various stages of development, and the numbers of students that can be admitted to the clinical practice of some of the hospitals are limited. Appointments of the house officer and registrar types in the hospitals and institutes provide the most valuable form of postgraduate education, and there are opportunities for research for selected graduates. At all the institutes courses of instruction are given throughout the academic year; these are suitable for graduates in the early stages of their specialist education, and also for those who have completed their practical training. Two or more years of hospital work in general medicine and general surgery after graduation are normally advisable before beginning work in the special branches. The work at the institutes is of an advanced type, and is comprehensive enough to enable graduates with suitable practical experience to prepare for higher degrees and diplomas. Emphasis is placed on clinical and laboratory teaching, supplemented by lectures and demonstrations.

Brief notes are appended concerning each of these teaching bodies.

Postgraduate Medical School of London (associated with Hammersmith Hospital, Ducane Road, W.12).—Teaching in clinical departments based on ward work is continuous and is supplemented by lectures during three ten-weeks courses starting in January, April, and October. Course for university diploma in clinical pathology, lasting one year, available for limited number of selected students. Department of Radiology of hospital provides courses for D.M.R. of university and Conjoint Board. All these courses begin in October. Long-term and short-term tuition in anaesthetics provided for small number of students.

Institute of Cardiology (associated with National Heart Hospital, Westmorland Street, W.1).—Seven appointments of registrar type offered each year to physicians in training as cardiologists who already have a sound grounding in general medicine. General physicians may enrol for full-time or part-time instruction for one term of approximately three months. Three terms annually, beginning January, May, and October. Three intensive fortnight courses of lectures and demonstrations, beginning February, July, and November.

Institute of Child Health (associated with Hospital for Sick Children, Great Ormond Street, W.C.1., Hammersmith Hospital, and Queen Elizabeth Hospital for Children, Hackney).—Tuition provided throughout year in three terms of three months each, beginning January, May, and September. Series of lectures by specialists and experts each term.

Institute of Dermatology (associated with St. John's Hospital for Diseases of the Skin, 5, Lisle Street, W.C.2).—Clinical teaching in out-patient department twice daily. Facilities for study and tuition in pathological laboratory. Owing to restricted accommodation, no ward instruction as yet. Short course of lectures in summer months, more systematic course in winter. Clinical assistantships arranged for more advanced students.

Institute of Diseases of the Chest (associated with Brompton Hospital, S.W.3).—Students enrol for three months or more for what is at present approximately a half-time course. In special cases a whole-time programme can be arranged. Courses consist of clinical work in wards and out-patient departments, lectures, and demonstrations. Three terms annually, beginning January, April, October.

Institute of Laryngology and Otology (associated with Royal National Throat, Nose, and Ear Hospital, Gray's Inn Road, and Golden Square, W.C.1).—A comprehensive full-time course lasting 20 weeks is held twice a year, beginning in January and July. Part-time advanced revision course lasting 10–12 weeks, suitable for students preparing for higher qualifications, is held twice yearly,

approximately from February to May and from September to November. A number of appointments open to students after completion of basic training in specialty, giving good opportunities for acquiring and extending clinical experience.

Institute of Neurology (associated with National Hospital for Nervous Diseases, Queen Square, W.C.1).—Teaching mainly by attendance on hospital practice; three terms annually. More advanced students appointed as clinical clerks in wards or attached to special departments and research laboratories Two whole-time courses in clinical neurology held annually in autumn and spring terms. During summer term a course in neurosurgery is held. Two courses of weekly clinical demonstrations held regularly.

Institute of Obstetrics and Gynaecology (associated with Queen Charlotte's Maternity Hospital, Chelsea Hospital for Women, and Department of Obstetrics and Gynaecology, Postgraduate School).—Teaching based on ward work and supplemented by lectures and demonstrations during 10-week terms, beginning October, January, and April. Short intensive courses of a fortnight's duration, suitable for students preparing for higher qualifications, are held twice a year. Limited number of posts for junior specialists receiving advanced training.

Institute of Ophthalmology (associated with Moorfields, Westminster, and Central Eye Hospitals).—In addition to teaching by means of hospital practice, a routine lecture and tutorial course, lasting four to five months, is held twice a year, beginning March and October. This starts with basic subjects and elementary clinical instruction and proceeds to cover all branches of ophthalmology. Clinical teaching and lectures given at higher level for advanced students.

Institute of Orthopaedics (associated with Royal National Orthopaedic Hospital, Great Portland Street, W.1).—Practice of both central hospital and country hospital at Stanmore open to postgraduate students. Selected students have opportunities for taking active part in work of Institute and hospital and for spending in the Institute up to two years of their training. Comprehensive six-months basic course held each year, beginning in October. Twice a year, in April and September, a one-week course in advanced clinical orthopaedics is held.

Institute of Psychiatry (associated with Maudsley Hospital, Denmark Hill, S.E.5, and Bethlem Royal Hospital).—Training normally covers two to three years after experience elsewhere in general medicine, and is based on responsible hospital duties under supervision. Regular series of lectures and demonstrations given throughout each of the university terms; clinical training continues throughout the year and includes seminars and case discussions. Students who, because of previous experience, do not wish to take the comprehensive two-year course are able to attend limited series of lectures and clinical instruction. Facilities for original investigation under supervision in clinical departments and in the psychological, neuro-anatomical, electrophysiological, and biochemical departments.

Institute of Urology (associated with the combined school of St. Peter's and St. Paul's Hospitals, Henrietta Street, W.C.2) —Three courses of 14 weeks' duration held annually, beginning January, April, and September. An intensive two-weeks course suitable for students taking higher examinations is held in September and March. Limited numbers of clinical assistants are appointed in January and July each year. Two courses in venereology, each lasting four months, held annually, beginning April and September.

Institute of Dental Surgery (associated with the Eastman Dental Clinic, Gray's Inn Road, W.C.1).—Object of Institute is to train dental practitioners in the special branches of preventive and therapeutic dentistry, both for children and for adults, by means of clinical experience, lectures, demonstrations, and research. Opportunities for limited number of students available in orthodontics, conservative dentistry, periodontia, and preventive dentistry, the courses varying from four to 12 months.

Prospective students should make their own arrangements well in advance. Those sponsored by their universities, governments, or other official bodies receive first consideration in the allotment of vacancies. Established specialists from overseas, here for a relatively short time, who wish to see something of practice in this country are always welcome: they are regarded as visiting colleagues, and the experts in their specialties are always ready to receive them and let them accompany them in their work and teaching. In addition refresher courses for general practitioners are arranged at non-teaching hospitals in London and the home counties. Inquiries should be made of the Federation at the address given above. An information bureau of postgraduate activities in London and other university centres is maintained.

The Fellowship of Postgraduate Medicine (1, Wimpole Street, W.1) provides general information on postgraduate work and arranges courses of instruction as follows: (1) Week-end courses at various hospitals in such subjects as infectious diseases, geriatrics, rheumatic diseases, and clinical surgery. (2) Courses specially suitable for, though not restricted to, candidates for the D.A., D.C.H., D.Obst.R.C.O.G., M.R.C.P., and F.R.C.S. (Primary and Final). These include general medicine, neurology, general surgery, proctology, obstetrics, children's diseases, and anaesthetics Some are full-time courses, lasting one to two weeks; others are spread over longer periods, arranged either in mornings, afternoons, or evenings, and are intended particularly for postgraduates who are not free for full-time study.

Facilities in Other University Centres

The following is a list, not exhaustive, of courses of postgraduate instruction held regularly at universities other than London. All are full-time courses, except those in general medicine at Liverpool and Sheffield, in neurology at Birmingham, and in obstetrics and gynaecology at Liverpool, which are part-time. All the courses include practical work, demonstrations, and lectures.

Courses in public health, which are provided by practically all the universities, are not included in this table. They will be found set out in the article headed "Special Diplomas."

Subject	University	Duration	Starts	Remarks
Anaesthetics	Bristol	12 months	Oct.	Suitable for D.A. (Conj.)
	Liverpool	12 ,,	,,	,, ,,
	Oxford	2 weeks	Mch., Sept.	Revision for D.A. (Conj.)
Bacteriology	Manchester	9 months	Oct.	For Dip. Bact. Manch.
Industrial health	Edinburgh	9 ,,	,,	For D.I.H. Ed.
	Glasgow	9 ,,	,,	For D.I.H. (Conj.)
	Manchester	9 ,,	,,	,, ,,
Medicine (general)	Edinburgh	12 weeks	Oct., April	Advanced instruction
	Glasgow	8 ,,	,, ,,	,, ,,
	Liverpool	10 ,,	Oct., Jan., April	Advanced revision
	Sheffield	10 ,,	,, ,,	,, ,,
Neurology	Birmingham	2 months	,, ,,	Revision suitable for D.P.M. (Conj.)
Obstetrics and gynaecology	Liverpool	5 ,,	Oct.	Advanced revision; 1 session weekly; first 15 weeks, obstetrics; second 15 weeks, gynaecology
Ophthalmology	Birmingham	6 ,,	Jan., July	Suitable for D.O. (Conj.)
Orthopaedic surgery	Liverpool	15 ,,	Oct.	For M.Ch.Orth. Lpool
Paediatrics	Bristol	3 ,,	,,	
Psychiatry	,,	2 terms	,,	For Part I, D.P.M. (Brist.)
	Edinburgh	5 weeks	,,	For Dip. Psychiatry (Ed.)
	Leeds	3 terms	,,	For Part I, D.P.M. (Leeds)
Radiodiagnosis	Bristol	18 months	,,	For D.M.R.D. (Brist.)
	Edinburgh	18 ,,	,,	For D.M.R.D. (Ed.)
	Glasgow	18 ,,	Oct., April	For D.M.R.D. (Conj.)
	Liverpool	2 years	Oct.	For D.Rad.(D.) and M.Rad. (Lpool)
	Manchester	18 months	April	For D.M.R.D. (Conj.)
	Sheffield	18 ,,	Oct.	,, ,,
	Wales	15 ,,	,,	,, ,,
Radiotherapy	Birmingham	2 years	,,	For D.M.R.T. (Conj.)
	Bristol	2 ,,	,,	For D.M.R.T. (Brist.)
	Edinburgh	2 ,,	,,	For D.M.R.T. (Ed.)
	Glasgow	2 ,,	Oct., April	For D.M.R.T. (Conj.)
	Liverpool	2 ,,	Oct.	For D.Rad.(T.) and M.Rad. (Lpool)
	Manchester	2 ,,	April	For D.M.R.T. (Conj.)
	Sheffield	2 ,,	Oct.	,, ,,
Surgery (general)	Edinburgh	5 months	Oct., Mar.	Advanced instruction
	Glasgow	8 weeks	Oct., April	,, ,,
	Liverpool	9 months	Oct.	For Ch.M. (Lpool), (suitable also for F.R.C.S.)
Tropical medicine	Edinburgh	2 terms	,,	For D.T.M. and H. (Ed.)
	Liverpool	4 months	Jan., Sept.	For D.T.M. and H. (Lpool)
Tuberculosis	Wales	6 ,,	Jan.	For T.D.D. (Wales)

At Cambridge postgraduate courses have been arranged as follows: October, 1949, to July, 1950: regular daily sessions at fixed times, taking the form of ward rounds, out-patient clinics and clinico-pathological conferences. In February, 1950, a postgraduate course in orthopaedics has been arranged. Information

about the Cambridge courses should be sought from the Secretary, the Naval Hut, Downing College.

Westminster Medical School celebrated its centenary in July with a postgraduate course for old students given by members of the staff of the Westminster group of hospitals. The first course for the final F.R.C.S. examination to be held at Westminster and the designated hospitals will take place in September and October.

A two-weeks course on child health is being held in Glasgow in September, and a three-weeks course on mental deficiency in October. In Durham a recent short course in midwifery and gynaecology, designed for practitioners, proved very popular, and it is hoped to run a second course later in the year.

The Royal Colleges

A highly important contribution to postgraduate education is by means of the series of lectures at the Royal Colleges. The Royal College of Physicians of London holds a series of lectures for postgraduates on advanced clinical subjects. The lecturers are specially distinguished in their respective fields and are drawn from the provinces as well as London.

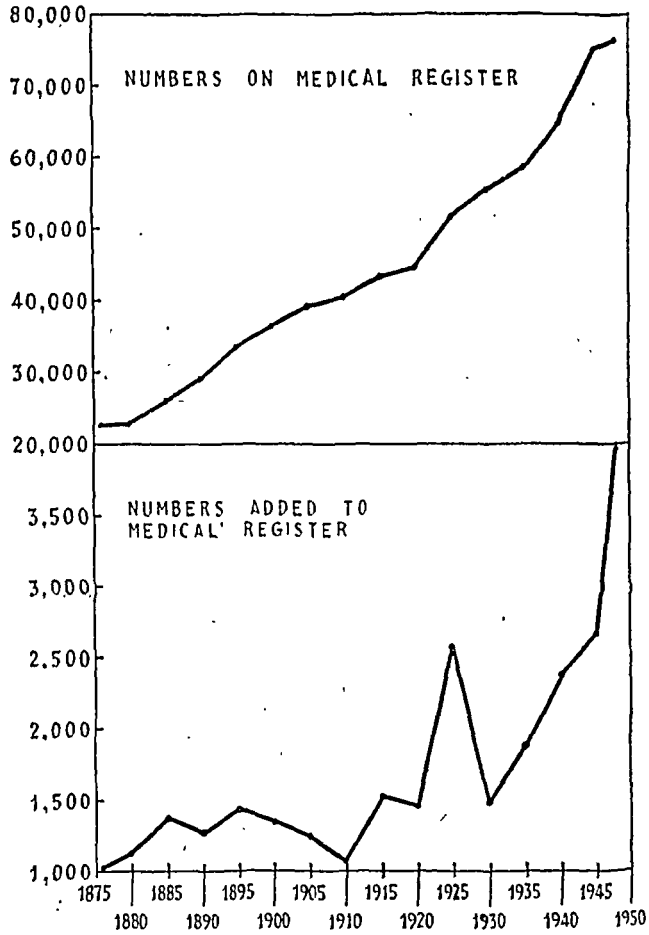
The Royal College of Surgeons of England has arranged a number of lectures and demonstrations to be held at the College. In surgery two series, each of 24 lectures, will be given during October and April, and at the same time clinical conferences will be arranged at selected hospitals. In anaesthesia two series, each of 45 lectures, will be given in October and March. In addition, courses extending over a period of from one to two years are being arranged. Between October and January and between March and May there will be a series of 72 lectures and practical demonstrations in anatomy, applied physiology, and pathology. Lectures in oral, dental, and general surgery will be given in February–March, and lectures and practical demonstrations on the application of the basic sciences to dental surgery will be held in January–February.

Facilities are now available for advice on postgraduate orthopaedic training through the Postgraduate Orthopaedic Committee which, with its headquarters at the College, has been established under the aegis of the Royal College of Surgeons of England, the Royal College of Surgeons of Edinburgh, the Royal Faculty of Physicians and Surgeons of Glasgow, the British Orthopaedic Association, the Institute of Orthopaedics of the British Postgraduate Medical Federation, and the Department of Orthopaedics of the University of Liverpool.

The British Medical Association, which last year published the report of its special committee under the heading *The Training of a Doctor*, has appointed another committee, again under the chairmanship of Sir Henry Cohen, to consider the postgraduate education of general practitioners.

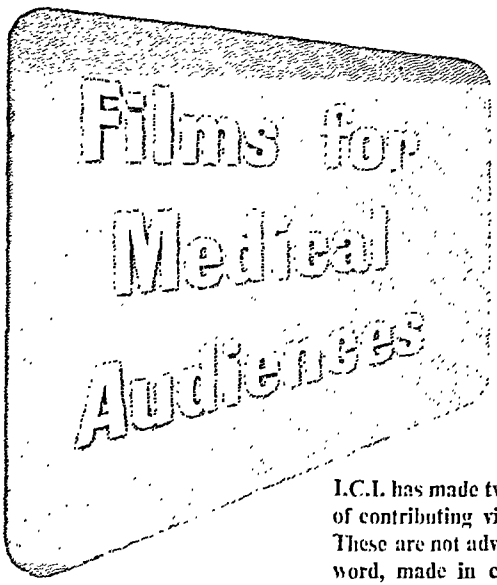
THE ENROLMENT IN MEDICINE

The total number of names in the current *Medical Register* is 76,292, a drop of 1,600 on the figure of a year ago, but 5,000 higher than the average of the last twenty years. Commonwealth and foreign registrations account for only 10% of the total. During last year the task of determining the position of practitioners eligible to apply for normal registration under the Medical Practitioners and Pharmacists Act, 1947, was completed, with the result that 4,467 names were removed from the temporary list. Of these practitioners, who came on to the *Register* from abroad mostly in the period 1941–5, just over 3,000 did not apply for re-registration under the Act just mentioned within the statutory time limit, and it may be assumed that most of them have returned to their practices in their own countries. Of the remainder, 1,337 have come on to the Foreign List of the *Register*.



The number of persons registered in the local registers for England, Scotland, and Ireland is 68,323; those on the Commonwealth List number 6,081, and those on the Foreign List, 1,803. Those temporarily registered number only 85. They are persons whose applications under the new Act have not been finally determined. As a result of this readjustment the number of names added to the Foreign List in 1948 is the highest recorded addition in any one year, as is also the number added to the Commonwealth List (416).

The following table gives the position in respect of the *Medical Register* during the last ten years:



Year	Added by Registration	Restored	Removed	Total number
1939	2,968	49	1,027	63,360*
1940	2,384	37	1,102	64,679
1941	3,296	16	996	66,992
1942	3,556	7	1,127	69,428
1943	3,532	13	1,091	71,882
1944	2,971	11	1,218	73,646
1945	2,666	11	1,190	75,133
1946	2,237	14	1,092	76,292
1947	2,787	10	1,160	77,929
1948	3,968	16	4,467	76,292

*Figure adjusted in 1940.

The following graph shows the numbers of medical practitioners on the *Register* at each five-yearly period since 1876, when the information was first compiled, and the numbers of additions. The large increase in the number added in 1948 is mainly due to the transference of temporarily registered foreign doctors.

The task of training students to be doctors is shared between the teaching hospitals and the universities. In London the twelve undergraduate teaching hospitals, each with its group of satellite institutions, have been designated as teaching centres. In the regional hospital centres of England and Wales the existing teaching hospitals, again with their groups of associated hospitals, have been similarly designated. The teaching hospitals remain separate from, though closely linked with, both the regional services and the university. They are specially picked centres for medical training, drawing their patients, of course, from a wider area than the ordinary hospital, but the board of governors of each teaching centre comprises nominees of the university, of the regional board, and of the doctors actually teaching in the hospital, as well as other persons

Available on free loan

I.C.I. has made twenty films on medical subjects as part of its policy of contributing visual aids to scientific and agricultural education. These are not advertising, but teaching films in the full sense of the word, made in collaboration with recognised authorities in the subjects dealt with. All the films listed below may be borrowed without charge by medical audiences who possess a 16 mm. sound film projector and have the services of a competent operator.

The Technique of Anaesthesia Series

Made in collaboration with the Westminster Hospital Medical School

16 mm. sound films—monochrome

Signs and Stages of Anaesthesia

Open Drop Ether

Nitrous Oxide—Oxygen—Ether Anaesthesia

Carbon Dioxide Absorption Technique

Endotracheal Anaesthesia

Intravenous Anaesthesia Part 1

Intravenous Anaesthesia Part 2

Spinal Anaesthesia

Respiratory and Cardiac Arrest

Operative Shock

Handling and Care of the Patient

*Anaesthesia in the Dental Chair (Adults)

*Anaesthesia in the Dental Chair for Children

**These two subjects made in collaboration with Guy's Hospital*

(A booklet with synopses of these films is available)

The following subjects are 16 mm. sound films in colour (Kodachrome):

The properties of acetylcholine

Made with the Department of Pharmacology, Oxford University

Physiology of the Kidney

Made with the Department of Pharmacology, University College, London

The Humoral Transmission of the Sympathetic Impulses

Made with the Department of Pharmacology, Oxford University

Perfusion of the Living Animal

Made with the Department of Physiology, Edinburgh University

Movements of the Tongue in Speech

Made with the Department of Phonetics, University College, London

Control of Infection in Surgical Dressings

Made with the Birmingham Accident Hospital

Further films are in course of production by the I.C.I. Medical Film Unit.

IN ANALGESIA

1540: "*Take a fatte piece of veale or ellse a fatte capon and boyle it in water or ellse white wyne and strayne it from the fleshe, and sett the saide lycor over the fyre agayn, and putt therto these things folowing, of mallowes ii. unces, of violett leaves, of night shade ana ℥ i. lett them boyle untyll they be very softe and tendre, and powre awaye the licor from them, and putt therto barley water as shall suffise to make it a pulthes*".

(A pulthes to cease payne devised by DR. BUTTS)

Today the physician has, in 'Physeptone,' a specific agent for the relief of pain. 'Physeptone' is more powerful than morphine and does not cause hypnosis or constipation. It may with advantage replace morphine as an analgesic for patients confined to bed. 'Physeptone' is available as 5 mgm. compressed products for oral administration (bottles of 25, 100 and 500), and as injection, 10 mgm. per c.c. (ampoules of 1 c.c., in boxes of 12).

'PHYSEPTONE'

Dispensing Packs

The operation of the recently introduced concession on dispensing packs now makes available the fine therapeutic products of William R. Warner and Co. Ltd., for prescribing, both to N.H.S. and private patients, free of purchase tax.

Dispensing packs in the sizes shown are available free of tax for prescription and for Surgery use.

DISPENSING PACK SIZES

NOT subject to purchase tax when used on prescription

★AGAROL . . . . 14 oz. bottles	GELUSIL . . . . . 500 tablets
★ALKA-ZANE . . 4 oz. bottles	VEGANIN . . 100 & 500 tablets
ANUSOL . . 100 suppositories	VERACOLATE . . 500 tablets

★Agarol and Alka-Zane are dispensed by the chemist in unopened bottles, therefore, prescriptions should be for the sizes mentioned:—

℞ Agarol ʒxiv Sig. ʒphora somni.	℞ Alka-Zane ʒiv Sig. 3 t. i. d.

Note—Agarol and Alka-Zane for dispensing must be supplied in packs of 6 bottles and 3 bottles respectively to retail chemists and dispensaries.

William R. WARNER and Co. Ltd.

POWER ROAD, LONDON, W.4

appointed by the Minister in consultation with local health authorities and other interested bodies. In Scotland hospitals are not designated as teaching hospitals, and they all come within the jurisdiction of the five Regional Hospital Boards, but special provision is made for the inclusion in the boards of management of these hospitals of nominees of the university on which the region is centred and also of the teaching staff of the hospitals. In Northern Ireland there is a duty upon the Hospitals Authority—a body corporate appointed by the Minister of Health and Local Government—to provide the Queen's University of Belfast with adequate facilities for medical teaching.

The Student Entry

The number of medical students admitted to the schools of Great Britain and Ireland during the academic year 1948–9 was 2,653.

The table of student admission for recent years is as follows .

1941–2	2,361	1945–6	2,610
1942–3	2,468	1946–7	2,553
1943–4	2,426	1947–8	2,797
1944–5	2,612	1948–9	2,653

Passes and Rejections

The number of passes and rejections in the final or qualifying examinations held in 1948 by the various examining bodies was as follows :

	Passes	Rejections
Medicine	2,774	1,521
Surgery	2,756	1,805
Midwifery	2,909	1,536

The proportion of passes in medicine was highest in Sheffield (85.19%), in surgery in Aberdeen (87.21%), and in midwifery in St. Andrews (89.39%). The lowest proportion of passes in medicine and in midwifery (47.35 and 51.61% respectively) was in the Scottish Conjoint Board examination, and the lowest in surgery (47.29%) in the Society of Apothecaries, London.

In the examinations in anatomy and physiology the highest percentage of passes was in Sheffield (97.26%). The percentage of passes in the English Conjoint Board examination in these subjects was not much above 60, and in the Scottish Conjoint Board it was as low as 40.

The following table, which has been compiled from the report of the University Grants Committee (H.M.S.O., 1949), shows the numbers of professors and other teachers in the London medical schools.

Institution	Professors	Readers, Assistant Professors, and Independent Lecturers	Lecturers	Assistant Lecturers and Demonstrators	Others
Charing Cross Hospital Medical School	4	2	1	8	—
Guy's Hospital Medical School ..	8	5	8	19	—
King's College Hospital Medical School	2	1	5	4	—
London Hospital Medical School ..	7	7	12	8	—

British Postgraduate Medical Federation	9	5	47	13	12
London School of Hygiene and Tropical Medicine	11	5	13	4	1

Forthcoming Academic Year

The applications of students for 1949–50 are reported by many of the schools to be again well above the number which can be regarded as optimum, but owing to accommodation difficulties or for other reasons a strict limit has to be placed upon the number accepted. The London Hospital Medical College is receiving about 2,000 applications every year, and from these it has to select 80. At Middlesex, where again the intake is 80, there is no diminution in the number of applicants, and selection is a difficulty. At St. Bartholomew's the number of applicants is as high as, or higher than, ever, but the entry next October has been reduced to approximately 100. The Dean of Westminster Hospital Medical School writes that the number of students has mounted steadily to the present total of 140, and the problem of selection from the enormous number of applications is becoming increasingly difficult. At St. Mary's Hospital Medical School, 70 students—56 men and 14 women—were accepted for entry last session, and the number is expected to be about the same for 1949–50. The total number of full-time students in the school is about 440. The annual intake at King's College Hospital Medical School is 50, and students are admitted for clinical training twice a year, in April and October. At Guy's there are 80 vacancies to the preclinical studies, of which roughly two-thirds are for the first year, the remaining third entering the second year, having already passed the first M.B. In addition, 25 places are reserved for Oxford and Cambridge men for the clinical period of studies; these men take a three-months preliminary course before entering the wards.

In the provincial schools it is much the same story. At Leeds the intake into the first M.B. course cannot be increased beyond 75 without further building, and the selection of this number of students from the many hundreds of applicants is a difficult matter, but selection is still done by interview and consideration of scholastic performance. At Oxford the number of new students is restricted by decree; the number for the coming year has been fixed, as it was last year, at 55 men and 10 women. Ex-Service men and women are admitted over and above these numbers only if they were born before 1929. The various colleges put forward the names of the students they wish to be admitted to the medical school, and preliminary acceptance by a college is essential for any prospective student. The last annual entry at Cambridge was 210 new students, of whom 19 were women. At Bristol the annual entry is about 54, and the total number in Faculty 325. At Manchester and at Liverpool the annual entry is round about 100, representing the maximum capacity. About one-fourth of the students at Manchester are women. At Sheffield the figure is 60. In the Welsh National School of Medicine the number of places for entrants is now 65, comparing with 44 a few years ago, but this number falls short of the demand from the schools and from ex-Service men, and cannot be increased without extensive building, of which there is no early prospect. In the University of Durham the number of applicants is greater than ever before, and selection of the most suitable candidates to fill the 95 vacancies has accordingly been strict; women are accepted in the proportion of one to four.

In view of the hospital facilities available at St. Andrews the annual intake is limited to between 70 and 80 to ensure that each undergraduate receives adequate clinical instruction. At Glasgow it is expected that about 230 new students will ultimately be admitted. Queen's University, Belfast, admits 108 to the Faculty of Medicine, but this includes 20 dental students. Most of the places are allotted to students normally resident in Northern Ireland and children of former graduates. The number available for candidates from Great Britain and overseas is not likely to be more than ten, and for the coming session over 800 applications have been received.

Effect of National Health Service

A question which was asked of the deans concerned the effect of the National Health Service on the schools. In most cases the answer was that there was no perceptible effect. The Dean of the Medical College of St. Bartholomew's says that any effect of the N.H.S. on the College is not a direct one, but certain matters are requiring adjustment, not always in the College's favour, such as the ruling that whole-time pathologists must be paid wholly by the College instead of as hitherto by the College and the hospital. Similarly, the ruling that all registrars must be paid by the hospital instead of jointly by the hospital and College as hitherto has some serious implications, and the ruling is at the moment being contested.

Charing Cross says that the Service appears so far to have had little effect directly on the school, except to constitute it under section 15 of the Act as an independent legal entity, but even this has made little difference, as previously the school was organized on a basis similar to that now adopted. Middlesex says that the Service has had no appreciable effects. Certainly there has been no diminution of applications to join the school, and it enjoys all the same facilities in the hospital as before. St. Andrews says that, while the Service has had little influence upon undergraduate teaching, it has called for a complete reorganization of postgraduate instruction with a view to the training of specialists. The Dean of the Faculty of Medicine of Aberdeen writes: "So far as I can see, the only effect the National Health Service has had on the school is to continue the plethora of trainees imposed on us in the immediate post-war years. This should help in the teaching and guidance of students."

It should be made clear that medical schools are not transferred to the Minister or to the board of governors of the associated teaching hospital, but in the provinces they are owned and administered by the governing body of the university of which they form part, and in London by their own governing bodies. Any medical school of London University which was not a body corporate was required to become incorporated within six months of the passing of the Act.

Improvements in the Curriculum

Several schools report interesting changes in the curriculum. As mentioned last year, the Faculty of Medicine at Birmingham set up a committee to review the curriculum. During the past year this committee has confined its deliberations to the clinical course, and it has been decided to abolish the third and fourth M.B., Ch.B. examinations in their present form. The subjects formerly included in these two examinations have been transferred to the final examination, which is now divided into three parts—namely, (1) pathology, bacteriology, pharmacology, forensic medicine and toxicology, and social medicine, which will be taken in June of the fifth year; (2) surgery and obstetrics and gynaecology; and (3) medicine, paediatrics, and child health. The second and third parts of the examination, which also include applied pharmacology, pathology, and bacteriology, will be taken in June of the sixth year. Ophthalmology and psychological medicine have been deleted as separate subjects in the examination. These revised regulations apply to all students passing Part II of the second M.B., Ch.B. examination in and after March, 1949. The Dean states that a frequent criticism of the medical curriculum is that it is constantly being extended and the student's life is thereby made correspondingly difficult; therefore it is interesting that the lectureships in operative surgery, vaccination, and applied anatomy have been abolished. The experiment of teaching anatomy and physiology as an integrated subject continues to attract attention and congratulation.

At Leeds the revision of the curriculum with the object of giving the student a more integrated course is under active consideration. Entry requirements to the first M.B. course are being considered, with special reference to the new general certificate of education which in 1951 will replace the School and Higher Certificates. New regulations have been introduced for the Ch.M., for which a thesis must now be presented. At Bristol the main changes in the curriculum which have been introduced are, first, that a full introductory clinical course is now firmly established; and, secondly, that next year most of the systematic teaching in pathology will be given in the third and fourth years, so that the main instruction in this subject will be completed during the first clinical appointments. At Sheffield a new curriculum, to which reference was made in last year's account of the school, has been almost completely introduced, the last batch of students working under the old regulations having now entered their final year. In Durham the present arrangement of holding the second M.B., B.S. examinations in anatomy and physiology as separate parts is to be discontinued. In 1951 there will be a return to the system whereby the examinations in anatomy and physiology are taken together after five terms' work. A rearrangement of the final examination will also take place in 1950–1. Surgery is to be taken in Part II of the final examination in June of the final year, in company with medicine and paediatrics. Midwifery and gynaecology remain in Part I of the examination taken in the previous December.

At St. Andrews the six-year curriculum recommended by the General Medical Council was introduced last October, and the necessary rearrangement of work in the later years of study will be made as required. The whole curriculum may be taken at Dundee, or the first two years and two terms at St. Andrews and the remainder at Dundee. Good opportunities for clinical work are afforded by the Dundee Royal Infirmary and Maryfield Hospital, the instruction given thereat being recognized for purposes of graduation by all the Scottish universities, the universities of Cambridge and London, the National University of Ireland, and the Royal Colleges. It is the intention of the University to institute at an early date chairs in social medicine and in child health, so that in this respect the recommendations of the Goodenough Committee will also be fulfilled. At Manchester a Committee of the Faculty has spent a very long time considering the report of the B.M.A. Committee published last year under the title *The Training of a Doctor*, and several minor adjustments have been made. New regulations are also being introduced at Manchester for the final M.B., Ch.B. examination and the award of honours. At the University of Glasgow the recent recommendations of the General Medical Council will be implemented in the coming session, and all students commencing study in October or thereafter will follow a six-year curriculum, of which the first year will be devoted entirely to the pre-medical subjects.

The Welsh National School of Medicine has made some minor adjustments in the curriculum. The Senate has given much consideration to the Goodenough and B.M.A. reports and to the recent recommendations of the General Medical Council. The regulations for the degrees M.B., B.Ch.(Wales) are in the process of complete revision, with the object, among other things, of curtailing slightly the length of preclinical studies, lengthening the clinical part, and ensuring that the final examinations will all be taken near the end of the course. At the Queen's University of Belfast, under the new curriculum now in force, the second professional examination in anatomy, physiology, and biochemistry is taken after five terms of study, following upon which successful students pass on to two terms of study in pharmacology and bacteriology, ending with the third professional examination in these subjects.

King's College Hospital Medical School is in process of revising the curriculum, which will in future include the teaching of psychological medicine and certain special subjects such as orthopaedics and urology during the first twelve months of the clinical course. Three months will be devoted entirely to the study of paediatrics, including fourteen days in residence at the Belgrave Hospital for Children. A revision course will be held twice a year preceding the M.B., B.S. examinations. St. Bartholomew's reports no basic changes in the curriculum, but states that some developments have taken place putting rather more stress on the teaching of social medicine and allied subjects.

At St. Thomas's, which maintains its entry level of 80 clinical students a year, the elementary clinical period from October, including work in the casualty department, will be six months, after which the student will commence proper ward work as an in-patient medical clerk.

The Dean of the London Hospital Medical College (Dr. A. E. Clark-Kennedy) writes:

"I do not think there have been any great changes in the curriculum. We have, however, started a system by which all students are required to undertake duties in the wards for a period of 10–14 days during their clinical training—that is, at the end of their first clinical year. Students work eight hours in the wards every day, which they arrange with the ward sisters to suit their mutual convenience so as not to interfere with the lectures on the one hand and so that they go into the wards when there is most for them to do. They are expected to carry out any nursing duties which are to their educational advantage—that is, to carry out any nursing duties which they might find themselves required to *supervise* when later they are practising their profession. I would emphasize that they are not there to supplement labour in the wards. They are not expected to be asked to carry out work which has no educational advantage for them."

At St. Mary's Hospital Medical School a revised course of clinical lectures over a period of two years has been introduced, and it is expected that this will greatly assist the clinical students to cover the syllabus systematically. A chair in biochemistry has been instituted during the past session, and in October readerships are being established in anatomy, physiology, pharmacology, and bacteriology. Middlesex Hospital reports improvements in the clinical period, with a rearrangement of instruction in anaesthesia; and Charing Cross reports slight adjustments in the introductory clinical course.

The Older Universities

At Oxford the various colleges put forward the names of the students they wish to be admitted to the medical school, and preliminary acceptance by a college is essential for any prospective medical student. There are 22 men's societies in Oxford, each attached to a college and under the presidency of its head, and there are four women's societies attached to the three women's colleges and Lady Margaret Hall, and one non-collegiate society. Preliminary inquiries should be addressed to the head of a society, not to the Dean of the Medical School.

All students entering the school are now required to take the second public examination as before the war. The course normally taken to satisfy this regulation is the final honour school of animal physiology, which takes up one year after passing the anatomy and physiology examination for the B.M. degree. Students then do their clinical work either at the Radcliffe Infirmary in Oxford or at one of the teaching hospitals. Students who have completed their preclinical studies elsewhere are also admitted to the clinical school, though they take the qualifying examinations of their own universities.

At Osler House, in the Infirmary grounds, there is a club and hostel for clinical students, providing social and reading facilities and sleeping accommodation for those on duty in the hospital. This social, administrative, and teaching centre is being completed by the provision of additional lecture rooms and class-rooms and of further sporting facilities for students in the medical school.

In the University of Cambridge the most important plans concern the further development of the department of human oecology, in which a chair is to be established from October next. There is also a good prospect of an early start on the erection of a permanent building for the department, which it is hoped will be situated on Fenner's Ground and combined with a gymnasium suitable for remedial exercises. Here in an atmosphere of healthy athletic activity the University Health Service will have full scope. This service has been in operation during the past year and has carried out some 3,700 x-ray examinations and 1,700 clinical examinations on volunteers from among undergraduates and the university staff. The mass radiography apparatus and team have been borrowed from the East Anglian Regional Hospital Board. A high proportion of first-year students, men and women, have also submitted to a clinical examination. The results have been such as to suggest that at least x-ray examinations should be made compulsory. The new department of human oecology is also interested in the development within the teaching hospital of a home care and nursing service with which will be linked the study of the problems of the aged and infirm. The Reader in Human Oecology has been engaged in epidemiological studies and, in co-operation with the county medical officers of health, has been able to make a preliminary analysis of the distribution of infectious diseases in the schools.

The university department of radiotherapeutics has pursued research work designed to improve the treatment of cancer and allied diseases by the combined use of radiotherapy and chemotherapeutic agents. The department expects to have a 30 meV synchroton installed in the near future. The department of experimental medicine has carried out studies on various aspects of undernutrition, notably oedema, renal function, and skin conditions. The staff of Addenbrooke's, which has been strengthened by the election of a thoracic surgeon and a paediatrician, now regularly give courses on various special subjects for postgraduates, including general practitioners. The long vacation course in elementary clinical methods for undergraduates has been completely reorganized to cover adequately the intermediate period between preclinical and clinical work in accordance with the recommendations of the General Medical Council. Undergraduates also have the opportunity of attending an introductory course in psychology during the long vacation term of their residence.

During the past year the regulations for the Cambridge degrees in medicine and surgery have been revised. The most important change consists of a rearrangement of the final M.B. examination. Part I of this examination will in future include pathology, pharmacology, and therapeutics, instead of surgery and midwifery and gynaecology. Part II will include medicine, surgery, and midwifery and gynaecology, instead of medicine, pathology, and pharmacology and therapeutics. Under the new arrangements a candidate who fails in only one or two of the subjects in Part II will not necessarily have to sit the whole of that part again. The revised regulations apply to all candidates who matriculated after Oct. 1, 1948, but the new arrangements will begin on Oct. 1, 1951. At first most candidates who have matriculated before Oct. 1, 1948, will have the option of the old or new regulations.

Developments in London Undergraduate Schools

In discussing long-term and short-term developments at their schools many of the deans refer to the value of the arrangement whereby the main teaching hospital is the centre of a group of hospitals, most of them of a special type. University College Hospital, for example, has associated with it the Obstetric Hospital and the Royal Ear Hospital, Huntley Street, the Hospital for Tropical Diseases, and St. Pancras (formerly L.C.C.) Hospital. Guy's has the York Clinic and Nuffield House in its own curtilage, the Evelina Hospital for Sick Children, and country recovery and convalescent homes. St. Thomas's includes the Royal Waterloo Hospital for Children and Women, the General Lying-in Hospital, the Grosvenor Hospital for Women, and the Roffey Park Rehabilitation Centre.

Associated with the Royal Free Hospital group are the Elizabeth Garrett Anderson Hospital, the Hampstead General Hospital, and other institutions providing altogether over 700 beds, which are available for clinical teaching. The Royal Free is building a new wing in Hunter Street to provide additional laboratories, research rooms, and other conveniences to accommodate the increased numbers. At Westminster Hospital Medical School the clinical facilities available at the designated hospitals make it possible for an increasing amount of instruction to be given outside Westminster Hospital itself, and thus to deal more easily with the growing number of undergraduates. Students on general firms already attend All Saints' Urological Centre; the paediatric work is carried out at Westminster Children's Hospital; and a new surgery firm will shortly be formed to work at the Gordon Hospital. The teaching of psychiatry has been reorganized, and students attend for instruction at Netherne, Belmont, and Fountain Hospitals. There is a resident fevers course at the Western Hospital. A fortnight's resident course for final-year students has also been instituted at King Edward VII Sanatorium, Midhurst, where the students attend in groups of four. Only in the teaching of pathology has the problem of overcrowding arisen, and this has been solved by spreading instruction in that subject over a longer period of the clinical course. At Middlesex Hospital visits are arranged to Harefield Sanatorium, where lecture-demonstrations in pulmonary tuberculosis are given.

Although major building seems to be out of the question, many schools are making adaptations. At St. Mary's during the past year new research laboratories have been equipped in the biochemistry department and medical unit. A new common-room for women students, who make up a quarter of the intake, a new kitchen for the students' restaurant, and a photographic department for the combined use of the medical school and hospital have been opened. At King's College Hospital Medical School the post-mortem department has been re-equipped to provide better accommodation for post-mortem demonstrations, the museum is being recatalogued and many specimens remounted, and library facilities have been increased. At St. Bartholomew's the future plans are largely concerned

with rebuilding, and a start has been made on this with the help of the good offices of the University Grants Committee. The plans for the new Charing Cross Hospital and Medical School to be built at Northwick Park, Harrow, have now been submitted to the Ministry of Health and the University. Negotiations are almost complete for a lease of additional accommodation at Charing Cross, which will ease the pressure on the present facilities of the school until the move is made to Harrow. Middlesex Hospital School began its rebuilding before the war, but so far has not been able to resume this arduous task, though it is hoping to start again as soon as practicable.

The West London Hospital Medical School, by arrangement with the University of London, has agreed to accept no more undergraduate students. The last group of students entered the school in October, 1948. The usual undergraduate work will continue until these students have qualified, and early next year a start will be made with postgraduate teaching in association with the Postgraduate Medical School at Hammersmith. The plans for the future have not yet matured, but the full resources of the school and hospital will be devoted to the postgraduate training of specialists in medicine and surgery as soon as the school's undergraduate commitments have been fulfilled.

Schools Outside London

At the Medical School, Birmingham, the anatomical and dental hospitals are being reconstructed so that self-explanatory demonstrations may be presented to students from time to time. By a redistribution of space greatly increased accommodation has been made available for the teaching of surface anatomy. The building of the experimental anatomical research laboratory is proceeding slowly, but it is hoped that it will be ready for occupation in the near future.

On the clinical side at Birmingham a satisfactory year has been completed, and the Regional Hospital Board has given many examples of its desire to co-operate with the university by providing members of the university teaching staff with opportunities for practice and for teaching in the hospitals which are under its authority. A standing joint committee consisting of representatives of the university, the board of governors of the teaching hospital, and the Regional Hospital Board has been formed to ensure this close collaboration.

A new departure in the department of bacteriology is the introduction of an Honours (B.Sc.) School, which will help to meet the urgent need in medicine as well as in agriculture and industry for persons with knowledge of the principles of bacteriology and with practical experience of bacteriological technique. Research workers from the department of chemistry and paediatrics are working in this department on problems connected with tuberculosis. Mention should also be made of a further innovation which has taken place at Birmingham since the closing months of 1948—namely, an investigation into the condition of the chronic sick to determine whether the lot of these patients can be alleviated and to encourage them to return to some degree of active life. This inquiry is taking place at one of the hospitals under the authority and with the enthusiastic support of the Regional Board.

At Leeds accommodation has proved insufficient in the medical school for the needs of new and growing departments, but it has been possible to convert houses in the neighbourhood to accommodate the departments of preventive medicine and public health, forensic medicine, and paediatrics, while the departments of medicine and biochemistry have also taken over additional premises. This new accommodation will improve facilities both for teaching and for research.

The main advance in the medical school at Bristol next year will be the opening of a school of veterinary science under the aegis of the Faculty of Medicine. Twenty-five students are being admitted in October for the first-year course for the degree of B.V.Sc. Buildings to accommodate veterinary anatomy and physiology are nearing completion, and a farm for clinical work is being stocked and equipped.

At Sheffield the use for teaching purposes of hospitals other than those under the control of the board of governors is being steadily developed, and several members of the specialist staff of the City General Hospital have been recognized by the university as clinical teachers. A chair in social and industrial medicine has been set up, the student outlook on public health has been reorientated, and the research side of this department is being developed. The early history of the school has lately been recalled by Sir Arthur Hall's presentation of a portrait of Lord Addison, the first occupant of the Arthur Jackson chair of anatomy.

At Cardiff the University of Wales, the Welsh National School of Medicine, and the Regional Board have given much time and thought during the past year to the acquisition of a site for a new medical teaching centre, but so far without success. The reallocation of beds in the two main teaching hospitals—Cardiff Royal Infirmary and Llandough Hospital—is proceeding and should make it easier to use the beds at Llandough, which is a former municipal hospital, for teaching.

Proposals have been made in Wales to establish a whole-time chair and department of paediatrics and child health and to set up other special university departments. The university and the school are in sympathy with such developments and hope to proceed with them in an orderly fashion as money becomes available. In this connexion it may be mentioned that the co-ordination of the anaesthetic service in Cardiff and neighbourhood through a medical school appointment has led to a great increase in efficiency and to the development of research and improvement of methods which are attracting many postgraduate students and visitors from foreign countries.

At Edinburgh from October, 1948, the course for the M.B., Ch.B., previously five years, was extended to six.

The School of Medicine in the University of St. Andrews lays stress on the value of residence. Both at St. Andrews and at Dundee there are excellent student residences which accommodate undergraduates from all or any of the faculties. Medical students in their early years are encouraged to reside in these, so that there is a width of contact among the undergraduates which is of great educational value. In addition there is the William Low Residence of Medical Students, situated near the principal teaching hospital, which is devoted exclusively to undergraduates in their clinical years.

At Queen's University, Belfast, clinical teaching is carried out at the Royal Victoria Hospital (554 beds), the Mater Infirmorum Hospital (200 beds), the Belfast City Hospital (600 beds), and the other hospitals in Belfast which deal with specialties. A new department of child health under the care of a full-time professor has been established, and the department of social and preventive medicine (formerly the department of public health) has been reorganized to meet the requirements of the General Medical Council. The erection of a new clinical block and an extension of the institute of pathology have been sanctioned and it is hoped to begin construction this year. A full-time officer in charge of students' health has been appointed at Belfast, and all first-year students are required to be medically examined, the examination to be repeated before entering upon clinical studies.

So much for a review of undergraduate education. One fact has not up to now been mentioned, but it is everywhere felt—namely, the handicap arising from the calling up of men so soon after qualification. By the time they are out of the Services again they are often married or for other reasons are not prepared to come back as house officers. It is certainly unfortunate that at the present time military service is seriously handicapping the normal postgraduate education of the medical student.

On a still broader issue perhaps we may quote again the Dean of the London Hospital Medical College :

> "I suppose the major problem is how medicine should be taught in the face of the increasing volume of medical knowledge and the increasing complexity of the practice of medicine. It seems to me that before long we shall reach bursting point, and some radical reconstruction will be necessary. Personally I think too much time is given to preclinical subjects, and before long clinical training must be brought back into the preclinical period, and the men started in the wards sooner, and the teaching of anatomy and physiology carried on during their clinical training so as to provide some satisfactory overlap.
>
> "But perhaps I am a heretic in these things."

QUALIFYING DEGREES AND DIPLOMAS

All universities, following the results of the final examinations, confer qualifying bachelor degrees in medicine and surgery. The abbreviations for registration are: B.M., B.Ch., U.Oxfd.; M.B., B.Chir., U.Camb.; M.B., B.S., U.Durh. and U.Lond.; M.B., Ch.B., V.U.Manc., U.Birm., U.Lpool, U.Leeds, U.Sheff.; U.Brist., U.Edin., U.Aberd., U.Glasg., and U.St.And.; M.B., B.Ch., U.Wales, N.U.Irel., Q.U.Belf., and U.Dubl. (also L.Med. and L.Ch., U.Dubl.). The licentiateship in medicine, surgery, and midwifery of the Society of Apothecaries of London (L.M.S.S.A.Lond.) also admits primarily to the *Register*, as does the licentiateship of Apothecaries' Hall, Dublin (L.A.H.Dubl.). The Medical Act, 1886, requires the document presented in evidence of any of the above qualifications to show that its holder has passed a qualifying examination in medicine.

The Conjoint Board

The qualifying diplomas in the English Conjoint (L.R.C.P. Lond., M.R.C.S.Eng.) were taken by about one-fifth of the total of those who qualified last year. Candidates are examined by the Examining Board in England of the three Royal Colleges (Examination Hall, Queen Square, W.C.1). Three examinations have to be passed: a pre-medical examination; a first examination in anatomy, physiology, pharmacology, and materia medica; and a final examination in pathology and bacteriology, medicine, surgery, midwifery, and gynaecology. Candidates are required to complete the medical curriculum extending over not less than fifty-seven months of study at recognized medical schools and hospitals, and to pass the professional examinations in accordance with the regulations after passing any two parts of the pre-medical examination. The Board does not itself conduct the preliminary examination in general education but recognizes a number of matriculation examinations and school-leaving certificates.

The examinations of the Board are conducted four times a year, and candidates are required to give notice to the secretary of the Board twenty-one days before the examination. The first medical examination is in two parts: (1) anatomy and physiology, written, oral, and practical; and (2) pharmacology and materia medica, oral only. In the final examination, medicine, surgery, and midwifery and gynaecology are written, clinical, practical, and oral; pathology is written and oral only, and may not be taken alone as the last part of the examination.

Candidates who produce evidence of not less than twenty-seven months' recognized clinical study subsequent to passing in anatomy and physiology are admissible to any one part only of the examination; on the completion of thirty months' study they are admissible to one or two further parts, or to three parts if presenting themselves for the first time. Candidates may not enter for the last part of the examination until they have completed thirty-three months' clinical study. Before admission to the final examination candidates must show that they are at least 21 years of age and must produce evidence of having completed the medical curriculum as set out in the regulations.

The Scottish and the Irish Conjoint

The Royal College of Physicians of Edinburgh, the Royal College of Surgeons of Edinburgh, and the Royal Faculty of Physicians and Surgeons of Glasgow have an arrangement by which after one series of examinations students may obtain diplomas of the three co-operating bodies (L.R.C.P., L.R.C.S.Ed., L.R.F.P.&S.Glas.). Each of these corporations grants its single diploma after examination, but the single diploma does not confer the right to qualifying registration; it is only a qualification additional to those already on the *Register*. The course of professional study embraces a certified period of not less than five academic years, in the last three of which clinical subjects must be studied. The first examination embraces physics, chemistry, and biology; the second, anatomy and embryology, and physiology, biochemistry, and biophysics; the third, pathology, materia medica, and pharmacology. The final examination is in two parts: the first, forensic medicine and public health; and the second, medicine, surgery, and obstetrics and gynaecology. All candidates at the final examination must also produce certificates of efficiency in the practice of vaccination from a Government teacher in the United Kingdom. Candidates for the Scottish Conjoint may work at any of the medical schools of Great Britain and Ireland. Details may be obtained from the Registrar, 18, Nicolson Street, Edinburgh, 8.

The Conjoint Board of the Royal College of Physicians of Ireland and the Royal College of Surgeons in Ireland issues a joint licence in medicine, surgery, and midwifery (L.R.C.P.I.& L.M., L.R.C.S.I.&L.M.), which is a registrable qualification, and accepts candidates from most of the medical schools at home and overseas. The regulations are obtainable from the Secretary of the Conjoint Board, Royal College of Surgeons, St. Stephen's Green, Dublin.

Other Diplomas

The Society of Apothecaries of London, which was constituted by the Royal Charter of James I in 1617, confers a diploma (L.M.S.S.A.Lond.) which is registrable under the provisions of the Medical Act, 1886, and qualifies the holder to compete for appointments in the naval, military, and Air Force services and for civil and colonial appointments. Examinations for the final subjects are held monthly except in September. Examinations in anatomy, physiology, and materia medica are held in January, April, July, and October. Particulars from the Registrar, Apothecaries' Hall, Black Friars Lane, London, E.C.4.

The L.A.H. of the Apothecaries' Hall of Ireland (95, Merrion Square, Dublin) entitles to registration as a qualified medical practitioner under the Medical Act, 1886, and enables the holder to compete for public medical appointments, including naval and military service, civil and colonial appointments, and all Poor Law appointments. It entitles the holder to practise pharmacy as well as medicine, surgery, and midwifery, which means that he may if he so desires open a medical hall.

Diplomas in medicine and surgery registrable in the Colonial List are granted by the Universities of Sydney, Queensland, Adelaide, and Melbourne, Ceylon Medical College, University of Ceylon, University of Hong Kong, Royal University of Malta, Newfoundland Medical Board, University of New Zealand, the Universities of South Africa, Capetown, and the Witwatersrand, and the King Edward VII College of Medicine, Singapore. Under certain conditions diplomas of universities and colleges in some of the provinces of Canada are registrable; also, with some exceptions, and subject to dating, diplomas of the Universities of India and Pakistan and the University of Rangoon.

All universities confer the higher qualification of Doctor of Medicine and Master of Surgery. Liverpool also confers the degree of Master of Orthopaedic Surgery (M.Ch.Orth.U.Lpool). The regulations for the award of this degree have been amended. Intending candidates must now be holders of an F.R.C.S. or F.A.C.S. before beginning the course. The Irish universities offer the degree of Master of Obstetrics (M.A.O.). The Master of Surgery of Oxford is a degree admitting primarily to the *Register*; it is conferred as the result of an examination. To obtain the D.M., Oxford, a thesis satisfactory to the Faculty Board must be presented. University requirements vary, and particulars should be obtained from the one selected.

M.R.C.P.

The Royal College of Physicians of London confers its Membership (M.R.C.P.Lond.) by examination. The pass for membership is a written examination in the form of a paper on questions of medical anatomy, pathology, principles of medicine; a paper on questions of the practice of medicine, including the principles of public health, and on psychological medicine; a clinical examination in the clinical wards of a hospital; and oral examinations. The M.R.C.P. has been the subject of recommendations of a committee which considers that

> "Membership of the College should signify a knowledge of general medicine that justifies further training as a consultant and the examination should therefore be a test in general medicine on a level higher than that required for qualification."

Hitherto the M.R.C.P. has been looked upon as a qualification conferring specialist status. Fellowship of the College is subject to election by the Fellows.

Fellowships of the Royal Colleges

The Royal College of Surgeons of England grants its Fellowship (F.R.C.S.Eng.) to those who pass its primary and final Fellowship examinations. The primary examination, partly written and partly oral, is held in January and July, and the final examination, partly written, partly practical, and partly oral, and including the examination of patients, is held in May and November.

Membership of the Royal College of Obstetricians and Gynaecologists may be applied for by medical graduates who have been registered or eligible for registration for at least three years. The Fellowship (F.R.C.O.G.) is granted to members who are considered to have advanced the science and art of obstetrics and gynaecology.

The Royal College of Physicians of Edinburgh elects as a Member any licentiate of a British or Irish College of Physicians or any graduate in medicine of a university approved by the Council, following upon an examination in the principles and practice of medicine and also in a department of medicine selected and offered by the candidate and approved by the Council; in this a high standard of efficiency is expected. Examinations are held four times a year. Save in exceptional cases, no one is elected a Fellow of the College until he has been at least three years a Member. Motions for the election of Fellows are made at quarterly meetings of Fellows, and a three-fourths majority on ballot is necessary.

The Fellowship examination of the Royal College of Surgeons of Edinburgh consists of two parts: the first, a written paper and an oral examination in anatomy and physiology and in pathology and bacteriology; the second, a written paper, a clinical or practical examination, and an oral examination in the principles and practice of surgery, and in an optional subject chosen by the candidate from the following: surgical pathology and operative surgery; laryngology, otology, and rhinology; obstetrics and gynaecology; and ophthalmology.

The Royal Faculty of Physicians and Surgeons of Glasgow grants, after examination, a Fellowship *qua* physician and a Fellowship *qua* surgeon registrable by the General Medical Council as an additional qualification (F.R.F.P.S.G.). Admission is by examination and subsequent election. Candidates for the Fellowship in medicine must have been in possession of a recognized medical qualification for not less than three years and must have been engaged during one of these years in full-time clinical work in a recognized hospital and have spent two other postgraduate years in approved medical work. The examination comprises a clinical examination in medicine, written and oral examinations in the principles of medicine and medical pathology, and written and oral examinations in the practice of medicine and therapeutics. Candidates for admission to the Fellowship in surgery are required to possess a recognized medical qualification and to pass a primary and a final examination. The primary examination consists of written and oral examinations in anatomy, physiology, pathology, and bacteriology. For admission to the final examination candidates must have been in possession of a recognized medical qualification for not less than three years and produce evidence that they have been engaged, after qualifying, for one year in full-time clinical work in a hospital approved by the Council and a further two years in the study of surgery. The final examination comprises a clinical examination in surgery, written and oral examinations in surgical anatomy and surgical pathology, and written and oral examinations in surgery. Alternatively, candidates may submit themselves for examination in one of the following subjects: obstetrics and gynaecology, ophthalmology, and otorhinolaryngology. The address of the Royal Faculty is 242, St. Vincent Street, Glasgow, C.2.

The Royal College of Physicians of Ireland (6, Kildare Street, Dublin) grants to registered medical practitioners, as the result of examination, its Membership (M.R.C.P.I.), its Licence in Medicine (L.M.), and its Licence in Midwifery (L.Mid.). Dates and particulars of the examinations can be obtained from the Registrar. The College grants the Fellowship (F.R.C.P.I.). Only Members of the College are eligible for election as Fellows.

Two examinations—primary and final—are also required for the Fellowship of the Royal College of Surgeons in Ireland (St. Stephen's Green, Dublin). The first is in anatomy, physiology, and pathology, and the second in surgery. A one-year course for the primary starts in October each year and lasts three terms.

The Mastery of Midwifery of the Society of Apothecaries of London (M.M.S.A.) is designed to give evidence of practical experience in antenatal care, midwifery, and infant welfare, and their relation to hygiene and preventive medicine. The diploma indicates qualification to undertake the responsible control of maternity and child welfare. Examinations are held twice yearly, in May and November.

MILITARY SERVICE

Civilian doctors and released medical officers who have held a non-permanent commission in the Royal Army Medical Corps during the emergency will be considered for appointment to short-service commissions in the R.A.M.C. for a period of eight years. The first four years will be on the Active List and the remainder in the Regular Army Reserve of Officers. Civilian doctors will have direct appointment in the rank of lieutenant, and released medical officers, on certain conditions, in the rank of captain. Candidates must at the time of application be (*a*) normally not over 30 years of age, (*b*) British subjects or citizens of the Irish Republic, and sons of British subjects or citizens of the Irish Republic, and (*c*) registered under the Medical Acts in force in Great Britain and Northern Ireland. During their service on the Active List they will be considered for appointment to a regular commission, and if they do not want, or are not selected for, such commission they will receive at the end of their four years' short service on the Active List a gratuity of £600. Conditions of service and forms of application can be obtained from the Assistant Director-General, Army Medical Services (A.M.D. 1), 38, Hyde Park Gate, S.W.7.

On the nomination of the Central Medical War Committee (B.M.A. House, London) doctors are appointed to national service commissions in the rank of lieutenant. During their service they can apply for a short-service commission and subsequently be considered for a permanent commission under the conditions stated above.

Training of Army Medical Officers

Officers commissioned in the R.A.M.C. receive a postgraduate service training at the Royal Army Medical College, Millbank, S.W.1. Here a senior officers' course is held twice yearly. The first of the three parts is devoted to the study of tropical medicine and entomology, military surgery, pathology, military hygiene, and psychiatry, and is spread over about three months. Practical instruction and demonstrations are given concurrently with this part of the course. In addition there is a series of lectures on venereology, dermatology, the medical aspects of chemical warfare, and six visits to a recognized hospital. The second part includes clinical instruction in medicine and surgery at London teaching hospitals; this part also takes about three months. Examinations are held at the conclusion of each of these parts, and thereafter officers are selected for training in the specialist subject for which they are best qualified or show aptitude. The officers selected by the College Council for specialist training begin the third part in their particular subject after the completion of the six months devoted to the first and second parts. The training is carried out at various civil hospitals in London, Edinburgh, Glasgow, Belfast, Dublin, and other cities. The period of training is up to a maximum of twelve months, depending upon the previous experience in the specialty of the officer concerned. The examination consists of a paper of questions and practical or oral tests.

Instruction in tropical medicine includes a course of lectures and clinical demonstrations. In addition, instruction in entomology is given. The principles and practice of modern military surgery are taught at the College. Lectures in the various courses deal with the surgical lessons which have been learned as a result of war experience, and cover both general

and regional surgery. The surgery of tropical diseases has its place in the syllabus, and stress is laid on the influence of tropical diseases on the management of surgical conditions in the soldier both at home and abroad.

In the teaching of pathology the syllabus of lectures for the senior classes is designed to cover the subjects taught in the classes of tropical medicine, surgery, and hygiene. Specialists in pathology receive all their training, except in the performing of necropsies, at the College. The vaccine and serum departments, now separately accommodated at the emergency vaccine laboratory at East Everleigh, Wiltshire, are a part of the pathological department of the College and are responsible for the preparation of T.A.B. and cholera vaccines for the Army and of standard reagents for agglutination tests.

The hygiene department, in addition to the teaching of Army health, has facilities for the carrying out of research of importance to the Army from the hygiene point of view, and much work of this kind has been accomplished in the past and will be a feature of the activities of the College in the future. Well-equipped laboratories exist for instruction in hygiene laboratory work of all kinds. There is also a well-organized hygiene museum. Officers taking a specialist course in hygiene (now Army health) are given the opportunity of taking the D.P.H. and the D.T.M.&H., and a considerable part of the instruction for these diplomas is given at the College.

The course in psychiatry consists of lectures partly on clinical psychiatry and psychopathology and partly on the applications of psychological principles to morale, discipline, personnel selection, and other purely military matters. There are also demonstrations of clinical cases held at Banstead and Sutton Emergency Hospitals, and demonstrations of selection tests by a personnel selection officer.

SERVICE OVERSEAS

The Colonial Medical Service

An interesting career is offered by the Colonial Medical Service, vacancies in which occur in all parts of the Colonial Empire, the greatest number in tropical Africa and Malaya. Candidates must ordinarily be British subjects holding medical qualifications registrable in the United Kingdom, and should have had at least 12 months' postgraduate hospital experience before appointment. Those applying for entrance into the permanent service must be under 40 or 45 years of age, according to the age of compulsory retirement (50 in West Africa and 55 in most other territories) in the territory to which they are appointed. Contract appointments for short terms are available for candidates who are above the age limits or who, while being below the age, do not wish to commit themselves to a colonial career at the outset. Officers appointed to the permanent service are normally required to take a course in tropical medicine and hygiene either before proceeding overseas or during their first leave.

In the first instance medical officers are usually appointed for general duties, which require all-round ability and a balanced outlook upon both preventive and curative medicine. Such duties often involve the charge of a district hospital and responsibility for the medical administration of a district, although many officers are employed on clinical duties in the large hospitals. Some posts are purely concerned with public health work, and for these the possession of the D.P.H. or special experience in preventive medicine is necessary.

A large number of specialist appointments exist which are normally filled from within the service by officers possessing the necessary aptitude and qualifications. For these appointments a very high standard of professional attainment is required. Senior administrative appointments are also almost invariably filled by the promotion of serving officers. The Colonial Medical Service is unified throughout the Colonies, and promotion takes place in the administrative or specialist branches whether in the territory in which the officer is serving or on transfer to another. The scope for promotion is therefore considerable. The total of the establishments of the various Government medical departments amounts to some 800 European medical officers and an even greater number of officers appointed locally.

Officers possessing qualifications or experience in pathology would be considered for appointment to the laboratory establishments. Workers in the laboratories carry out pathological and biochemical examinations for clinical, forensic, and public health purposes. In this branch a great deal of the research work which has led to important advances in the knowledge of tropical medicine and of local health problems has been carried out.

There are a number of vacancies for women doctors, particularly for those with special experience in obstetrics, school health, child welfare, and nutrition, although their employment is not necessarily confined to these subjects.

Full particulars of terms and conditions of service may be obtained from the Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Medical Missions

To medical men and women with a sense of vocation and a desire to express their faith through their professional work, medical missionary service offers vast opportunities. In China, Christian missions have given the country a medical and a nursing profession, and even in these recent days of trouble and change the missions continue their witness. In Africa they have pioneered rural health services and contributed largely to leprosy research and control. In India and Pakistan they have helped to maintain high ethical and professional standards.

The missionary societies regard 18 months' postgraduate work in resident appointments as a minimum, and often advise work for specialist diplomas or higher degrees. In addition special missionary training is recommended. Terms of service vary in length from 18 months to six years, according to climatic conditions. Ordinarily it is hoped that life service will be volunteered for, but short terms are considered. Salary is on a missionary basis, with children's allowances and a pension scheme.

Applications from students and qualified men and women should be made direct to the missionary societies, through local branches of the Student Christian Movement or the Intervarsity Fellowship, or to the Chairman of the Medical Advisory Board of the Conference of British Missionary Societies, Edinburgh House, 2, Eaton Gate, London, S.W.1.

MEDICAL AUXILIARY SERVICES

In 1936, principally at the instance of the British Medical Association, there was formed a Board of Registration of Medical Auxiliaries. The purpose of the Board was to establish and maintain a national register of trained persons engaged in technical work or practice ancillary to the work of the medical profession. This register now comprises over 12,000 names and is composed of radiographers, dispensing opticians, chiropodists, speech therapists, orthoptists, dietitians, and physiotherapists and biophysical assistants. The Board is a registering and disciplinary body, not an examining one. Examining bodies in the various branches are approved by the Board and appoint representatives to its Council. The majority of members of the Council—nine out of 16—are members of the medical profession.

The function of the Board is to co-ordinate the work of these various auxiliaries, to ensure that they are qualified, to maintain and improve their standard of training, and to afford liaison between them and medical practitioners. All those whose names appear on the register hold a qualification in their particular sphere recognized and approved by the Board. With the exception of the chiropodists, all those on the register, as a condition of admission, undertake not to carry out any medical auxiliary work except under a medical practitioner's direction and control. The chiropodists, when not acting under medical direction, confine their practice to the treatment of malformed nails and superficial excrescences occurring on the feet, and bunions.

The qualifying bodies for the respective branches are the Society of Radiographers, the Association of Dispensing

Opticians, the Society of Chiropodists, the College of Speech Therapists, the British Orthoptic Society (the training and qualifications being the responsibility of the Faculty of Ophthalmology advised by the Orthoptic Board), and the British Dietetic Association. In 1944 the Chartered Society of Physiotherapy withdrew from membership of the Board, and so ceased to be a qualifying body. The Board is unable, therefore, to accept for registration members of the Chartered Society qualifying since that date, but the majority of the members, as distinct from the Society, registered with the Board have not resigned, and their names appear in the register. Biophysical assistants—namely, those qualified to dispense ultra-violet radiation, light, heat, etc.—underwent an examination formerly controlled by the Society of Apothecaries. This examination is no longer held, and the number of persons holding this qualification only is small. All the qualifying bodies have established periods of training. That for the radiographers, for example, is two years at a recognized training centre, and for speech therapists three years' full-time course at a recognized school.

The office of the Board is at B.M.A. House, Tavistock Square, W.C.1.

ORGANIZATIONS TO JOIN

At every gathering of final-year students and the newly qualified the man on the eve of entering practice, public or private, is advised to do two things—namely, to join one of the defence organizations and to become a member of the British Medical Association. This advice is as good as ever. The National Health Service has not made it less necessary for the practitioner, by joining a defence society, to protect himself against the medico-legal hazards to which even the most careful and conscientious practitioner is exposed. The defence societies are three in number.

Defence Societies

The Medical Defence Union (49, Bedford Square, W.C.1) has now a membership of over 33,200. It has thrown open its doors to dental as well as to medical practitioners, and it has made special provision for overseas medical and dental practitioners practising in the Dominions and in other countries. Its work has been increasing by leaps and bounds during the past three years. It claims to be the largest defence organization in Great Britain or indeed in any country except America. The Union furnishes advice and unlimited financial indemnity to any member threatened with or involved in litigation raising a question of professional significance or more commonly based upon a charge of professional negligence. The accumulated funds are now about £150,000, while the subscription income is mounting annually. Nevertheless, costs of litigation and of settlements out of court are mounting at a more rapid rate.

The Medical Protection Society, formerly known as the "London and Counties" (Victory House, Leicester Square, W.C.2), has a membership exceeding 25,000. During the past year it has gained nearly 1,800 new members. Membership is open to any registered medical or dental practitioner. This society was the first to afford indemnity against adverse costs and damages, the first also to afford unlimited indemnity. The indemnity is secured by financial resources exceeding £145,000 and a reinsurance at Lloyd's for an unlimited amount.

The Medical and Dental Defence Union of Scotland, Ltd. (115, St. Vincent Street, Glasgow, C.2), has a membership of approximately 6,200. The total assets are over £37,000. The policy of the council has always been to give careful consideration to the interests of its members who have claims made against them for negligence.

The annual subscription of all these societies is £1, with an entrance fee of 10s. The Medical Defence Union mentions the possibility of an increased subscription, but is prepared to accept newly qualified practitioners applying for membership within three years of their registration at the subscription of £1, this annual rate to obtain for the first three years of membership.

The British Medical Association

The British Medical Association (Tavistock Square, W.C.1) has now a membership of considerably over 60,000. It includes more than three-quarters of the members of the medical profession in the United Kingdom. Members are elected by the council of the Branch in the area in which they reside, or, if not resident in a Branch area (for example, serving with the Forces), by the Central Council. The privileges of members include participation in all activities, local and central, in its government and the formulation of its policy; the weekly receipt of the *British Medical Journal* and its *Supplement*; the use of the houses of the Association in London and Edinburgh, and the help of the central staff in professional matters. The Association offers a number of prizes for research and the encouragement of important work. Six prizes, each of the value of £25, are awarded annually to medical students for essays submitted in open competition on a national basis, and £150 has been allocated for the award of regional essay prizes to medical students based on the four regions of the British Medical Students' Association. The Association also has certain research scholarships which are awarded for a period of twelve months to accord with the academic year.

A recent development in the Association is the establishment of an Empire Medical Advisory Bureau to assist members of the profession coming to this country from the Dominions and Colonies for postgraduate instruction and other purposes. The Bureau, which is located at B.M.A. House, furnishes a personal advisory service to visiting practitioners, and one of its principal objects is to make available the fullest information regarding facilities for postgraduate study and, where necessary, to provide the required contacts and introductions.

A still newer piece of work of the Association is the establishment of a Medical Practices Advisory Bureau. The work of this Bureau is described elsewhere in this issue under the heading "The G.P. and the N.H.S."

The ordinary subscription to the B.M.A. for members resident in Great Britain and Northern Ireland is being raised from Jan. 1, 1950, to four guineas, but there are certain classes of members who come in at lower rates, and the newly qualified practitioner who is elected within two years of registration will pay only two guineas per annum for the period of four years after registration. Members residing outside Great Britain and Northern Ireland pay one and a half guineas, and Service members, wherever resident, two and a half guineas.

Medical Women's Federation

The Medical Women's Federation (Tavistock House North, W.C.1) is the only professional organization in this country consisting solely of medical women. Its forerunner, the Association of Medical Women, was constituted in 1879, but the Federation itself was founded in 1916. It endeavours to bring before the main body of the profession the special minority difficulties of medical women and, when necessary, to press for the full application of the principle of equality. It works in close and friendly relationship with the British Medical Association and encourages women to take an active part in the Association's central and divisional activities.

The Students' Association

The British Medical Students' Association (B.M.A. House, Tavistock Square, W.C.1) was founded in 1941 to afford a means of communication between medical students of the various schools and also between British and foreign medical students. It publishes a quarterly journal, organizes clinical conferences in university centres, and holds an annual meeting in London extending over a week-end. It has liaison with the Irish M.S.A. Last year it held a noteworthy International Clinical Congress in London, Oxford, and Birmingham; there were 107 delegates, representing 25 countries. The weakness of all students' associations is that they continuously lose members on graduation. The B.M.S.A., with the object of retaining the interest of its old members, has created a category of membership for qualified men and women, so that, having left the ranks of students, they are not necessarily cut off from the student body.

. . . . . for sleeplessness

trade mark 'SONERYL' the original brand of butobarbitone provides the ideal hypnotic for all cases of insomnia whether of mental or physical origin. It is rapid in action producing a natural dreamless sleep within half an hour, which is maintained from six to eight hours.

. . . . . where sleeplessness is associated with pain

trade mark 'SONALGIN' brand butophen with codeine combines the hypnotic properties of 'Soneryl' with the analgesic actions of codeine and phenacetin and is of particular value in the relief of pain in such conditions as dysmenorrhœa, neuralgia, myalgia fibrositis and migraine.

Supplies:

'Soneryl' tablets in containers of 12, 25, 100 and 500 x gr. 1½ (0.1 Gm.)

'Soneryl' *suppositories in boxes of* 5, each containing gr. 3, gr. 5, or gr. 10 of the active product

'Sonalgin' tablets
butobarbitone gr. 1 (0.065 Gm.),
codeine phosphate gr. 1/6 (0.011 Gm.)
phenacetin gr. 3½ (0.227 Gm.)
containers of 25, 100 and 500.

OUR BOOKLET 'MEDICATION WITH M&B BARBITURATES IN GENERAL PRACTICE' IN WHICH THESE PRODUCTS ARE DESCRIBED IS AVAILABLE ON REQUEST TO OUR MEDICAL INFORMATION DIVISION

PHARMACEUTICAL SPECIALITIES (MAY & BAKER) LTD., DAGENHAM

A convenient dietary supplement

'Radiomulsin' is a pleasantly flavoured emulsion containing in each teaspoonful vitamin A 2500 i.u., aneurine hydrochloride (vitamin B_1) 0.75 mg., riboflavine (vitamin B_2) 0.5 mg., nicotinamide 7.5 mg., ascorbic acid (vitamin C) 15 mg. and calciferol (vitamin D_2) 1000 i.u.

'Radiomulsin' is readily miscible with any type of infant feed. Its pleasant flavour appeals to children and adults and it may be administered undiluted or added to milk or other drink.

'Radiomulsin' contains the most important vitamins in the proportions most generally useful for the correction of vitamin dietary deficiencies in both young and old.

'Radiomulsin' is available in bottles of 4 and 16 fl. oz.

SPECIAL DIPLOMAS

Public Health

The London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1, offers a course of study for the University of London Postgraduate Certificate and Diploma in Public Health which begins in October and extends through an academic year of nine months. The preliminary part of the course, from October to December, which is followed by the examination for the C.P.H., is intended to meet the needs of registered medical practitioners who wish to devote themselves to any branch of public health work; and the full course provides more advanced instruction for those practitioners who wish to qualify themselves for appointments in which they are required by law to hold diplomas or degrees in public health or State medicine.

Students are also offered facilities for making special study of one group of subjects during the second part of a diploma course. These "elective" subjects have been introduced in order to give students an opportunity of acquiring special knowledge within the framework of the general course. The elective subjects offered are: (1) industrial health, (2) statistics, (3) hospital administration, and (4) tropical hygiene. The elective course in industrial health is recognized in part as qualifying for the examination for the Diploma in Industrial Health, and opportunities are given for visits to factories and other industrial establishments. Only a limited number of students can be accepted for this and the other elective courses.

At the University of Leeds the D.P.H. course covers three academic terms, of which the first is devoted to an introductory course in social medicine and the mass aspects of disease, on which the Certificate in Public Health is granted, followed by two terms of more detailed instruction in public health suitable for the practising medical officer. Practical bacteriology is taken in the course, so making it particularly suitable for those students who will ultimately practise public health in countries where the laboratory services are under the supervision of the public health service. The Department at Leeds is fortunate in having within a radius of 10 miles an area with a population of one and a half millions, both urban and rural, in which the practical field work can be particularly well undertaken. The Department of Preventive Medicine and Public Health has moved to new premises equipped with a demonstration room and a students' common-room for students attending public health courses of various kinds. In Durham a marked falling off in the number of applicants for the D.P.H. course led to its cancellation in 1948–9, but it is intended to provide a course, both for the diploma and the certificate, beginning in October, 1949.

At the Queen's University of Belfast a course for the Certificate and Diploma in Public Health is held each academic year in the Department of Social and Preventive Medicine. The courses, which are full time, are open to graduates of British and Commonwealth universities. Not more than 15 students are accepted, and priorities are given to graduates of Queen's University.

Full-time courses, with practical work, demonstrations, and lectures, lasting nine months and beginning in October, are also given at the Universities of Aberdeen, Birmingham, Bristol, Durham, Edinburgh, Glasgow, Liverpool, Manchester, St. Andrews, and Wales. Wales offers a three-months full-time course for the Certificate in Public Health, preliminary to the D.P.H., for which there is a twelve-months part-time course.

In addition to the universities, the Royal College of Physicians of London and the Royal College of Surgeons of England confer a Diploma in Public Health (D.P.H. R.C.P.S.Eng.), as do the Royal Colleges of Physicians and Surgeons of Edinburgh and the Royal Faculty of Physicians and Surgeons of Glasgow (D.P.H. R.C.P.S.Ed. and R.F.P.S.Glasg.), and the Royal College of Physicians and Surgeons in Ireland (D.P.H. R.C.P.S.I.). The University of Durham confers the diplomas of Bachelor and Doctor in Hygiene (B.Hy., D.Hy.Durh.), Birmingham that of Bachelor of Science in Public Health (B.Sc.(P.H.)Birm.), Glasgow similarly (B.Sc.(P.H.)Glasg.), as well as a doctorate, Victoria University of Manchester has a Diploma in Sanitary Science, and the University of Dublin a Diploma in State Medicine; all these in addition to the ordinary D.P.H.

The Royal Institute of Public Health and Hygiene (28, Portland Place, W.1) arranges courses of lectures and laboratory instruction for the D.P.H. Students completing the course are entitled to enter for examinations for the diploma of the universities and corporations. Examinations for the diploma and for the certificate are held twice a year.

Postgraduate teaching in the University of Liverpool includes full-time courses for the diplomas of D.P.H. and D.T.M.&H. (in conjunction with the Liverpool School of Tropical Medicine), as well as for the Diploma in Radiology referred to below.

Tropical Medicine and Hygiene

The Incorporated Liverpool School of Tropical Medicine has courses for the D.T.M.&H. Two courses are arranged for this diploma, each lasting about five months. The syllabus comprises tropical medicine, dermatology, ophthalmology, and surgery, bacteriology, entomology, parasitology, tropical hygiene, and sanitary engineering. Fees are 40 guineas for the D.T.M.&H. course and 20 guineas for the revision course. The examination in the University of Liverpool for this diploma is held twice yearly, in January or February and in April or May. The Liverpool School, which also gives courses of instruction in public health parasitology and entomology for students taking the D.P.H., has recently passed its jubilee.

The London School of Hygiene and Tropical Medicine offers a course in tropical medicine and hygiene, intended primarily to prepare qualified medical practitioners for the examination of the Conjoint Board for the D.T.M.&H. The courses last five months and there are two each year, from October to February, and from March to July, to prepare for the examinations in March and July. The syllabus includes systematic and practical instruction in the laboratory sciences, protozoology, helminthology, entomology, and bacteriology in relation to tropical conditions; theoretical and clinical instruction in tropical medicine, and systematic instruction in statistics, nutrition, sanitation, and public health. Application should be made not less than one month before the course is due to begin.

A short course in medical statistics is also offered by the London School. It occupies two days a week for three months, during April to July, and also during January to April if enough applications are received. The instruction is on the principles of medical statistics and statistical methods.

The Medical Faculty of the University of Edinburgh has courses for the D.T.M.&H.Edin., lasting two terms, beginning in October.

Industrial Health

The Royal Faculty of Physicians and Surgeons of Glasgow grants a Diploma in Industrial Health. Candidates for the diploma (D.I.H.Glasg.) must complete courses of instruction and pass the examinations. Copies of the regulations respecting the diploma may be obtained from the secretary of the Royal Faculty, 242, St. Vincent Street, Glasgow, C.2.

The Society of Apothecaries of London holds an examination for the Diploma in Industrial Health, taking the history of the subject, legislation, occupational diseases, the industrial environment, the practice of industrial medicine, and clinical medicine and surgery as applied to industry. The examination is held in July and December. The D.I.H. is granted by the University of Edinburgh and by the Conjoint Board.

The Royal Institute of Public Health and Hygiene arranges courses for the D.I.H.

Bacteriology

A course of study for the academic postgraduate Diploma in Bacteriology of the University of London is given by the London School of Hygiene and Tropical Medicine. The course extends throughout the academic year, starting in October. Lectures and practical instruction cover the fields of general

bacteriology, including the study of virus diseases and bacteriology applied to hygiene, and instruction is given in bacteriological chemistry, medical mycology, and elementary statistics. The course, which is intended to give advanced instruction in bacteriology to students who wish to follow a bacteriological career, may be taken by students with a qualification in medicine or veterinary science. A small number of students with an honours degree in science (including chemistry) or a degree in pharmacy may receive instruction in bacteriological chemistry as applied to industry instead of in bacteriology as applied to hygiene. The total number of places available in the course is strictly limited. Applications for admission to the course beginning in October must be received by the preceding March.

Manchester University also has a Diploma in Bacteriology.

Other Diplomas

A large number of other special diplomas are available, and the programmes and prospectuses of the various bodies must be consulted. The English and Irish Conjoint and several of the universities, among them Bristol and Leeds, have Diplomas in Psychological Medicine. The Diploma in Psychiatry of the University of Edinburgh (D.Psych.Ed.) requires candidates entering for the examination to have spent a period of three years in a duly proportioned training in approved hospitals, clinics, and other institutions.

Diplomas in Radiodiagnosis and Radiotherapy are conferred by the Conjoint Board and, among other universities, by Edinburgh and Bristol. A Diploma in Radiology (diagnosis and therapy) has lately been instituted in the University of Liverpool. Holders of this diploma (Dip.Rad.) may be awarded the degree of M.Rad. after further study for two years and the presentation of an acceptable thesis.

The University of Oxford grants a Diploma in Ophthalmology, the University of London a Diploma in Clinical Pathology. A Diploma in Anaesthetics is granted by the English Conjoint (D.A. R.C.P.Lond., R.C.S.Eng.), which also offers Diplomas in Laryngology and Otology, in Ophthalmic Medicine and Surgery, and in Child Health. Diplomas in Ophthalmic Medicine and Surgery, in Anaesthetics, and in Child Health are also granted by the Irish Conjoint.

Fellowship in Radiology

The Faculty of Radiologists (45, Lincoln's Inn Fields, W.C.2) offers a Fellowship (F.F.R.) to medical graduates of five years' standing who have spent at least one year in general clinical work at approved hospitals, hold a radiological diploma, and have practised radiology exclusively for at least two years after obtaining that diploma. Candidates are required to pass an examination and submit a thesis. Candidates who hold higher medical or surgical qualifications may be exempted from the examinations in general medicine, general surgery, or pathology.

COURSES IN PSYCHIATRY

The National Association for Mental Health (39, Queen Anne Street, W.1) arranges training courses in certain aspects of psychiatry, especially child psychiatry. Its courses for school medical officers are full. Fellowships are given to enable qualified psychiatrists to obtain special training in child guidance at a recognized training clinic and are tenable at a number of clinics in Great Britain. The usual course of training covers 12 months, half-time, and is recognized as a qualification for the medical directorship of a child-guidance clinic.

The Tavistock Clinic (2, Beaumont Street, W.1) specializes as a centre for the out-patient treatment of children and adults with psychiatric disabilities. The educational programme includes courses for psychologists and social workers as well as doctors. It organizes with the National Association for Mental Health (see above) the 12-month half-time course for psychiatrists specializing in child psychiatry.

The Institute of Psycho-Analysis (96, Gloucester Place, W.1) furnishes a part-time course, lasting about four years, in psychoanalytic theory and technique. It includes a personal analysis, attendance at lectures and seminars, and clinical work under supervision. The Institute does not set out to teach all aspects of psychiatry, and general psychiatric experience must be obtained at other clinics and hospitals.

The Institute of Psychiatry, associated with the Maudsley Hospital and Bethlem Royal Hospital, is referred to in the article on "Postgraduate Training Facilities" (p. 530). Training normally covers a period of two to three years after adequate experience elsewhere in general medicine and is based on responsible hospital duties under supervision. The aim is to provide a wide training in the many branches of clinical psychiatry and its basic sciences.

The fees payable by those who attend the teaching at the Institute of Psychiatry without holding hospital appointments are: for clinical instruction only, 10 guineas for three months, 15 guineas for six months, and 20 guineas for 12 months; for clinical instruction and all first- or second-year lecture and demonstration courses, 20 guineas for one term and 50 guineas for one year; and for first- or second-year lecture and demonstration courses only, 12 guineas for one term and 30 guineas for one year. The enrolment fee is £1. Fuller information may be obtained from the Dean, Maudsley Hospital, Denmark Hill, S.E.5.

NEW WORK FOR THE KING'S FUND

King Edward's Hospital Fund for London is not directly affected by the National Health Service Act (it is governed by an Act of its own, passed more than forty years ago), and its responsibilities and sphere of influence have been enlarged, not diminished, as a result of the transfer of hospitals to the Minister of Health. The King's Fund has been in the past a staunch supporter of the voluntary system, and its aid enabled this system to survive the financial crisis which followed the first world war.

Now that the voluntary system has been abolished the King's Fund remains as a residuary legatee. There is, as its 52nd annual report points out, still a large volume of good will flowing towards hospitals, and the Fund offers a means whereby in the metropolitan area this can be canalized. The Fund has large financial resources, its ordinary income reaching over a quarter of a million pounds, 90% of which comes from investments. What is more important, it has a long and intimate experience of hospital problems. It would be premature to define precisely the manner in which this income may still be used to assist hospitals, but there are many ways in which institutions can be helped, though the State is financially responsible for their maintenance. Last year, for example, grants amounting to over £21,000 were made to some fifty hospitals for the provision of comfortable modern mattresses. Other grants were made for the well-being and comfort of patients and staff by providing patients' trays, easy chairs, wireless, and so forth; for improving the hospital service by gifts of refrigerators, washing machines, and *x*-ray apparatus; and to encourage the extension of the work done by hospitals for the aged and the chronic sick.

Little attention has been paid to the "disclaimed" hospitals, but, as the report points out, the progress and development of the National Health Service will be profoundly influenced by the existence of active institutions experimenting and developing under voluntary aegis. Grants to twelve such hospitals in the metropolitan area were made last year. Convalescent homes also require help, and a sum of £30,000 was distributed among them during 1948. In some respects the new Act is a greater landmark in the history of convalescent homes than of hospitals, because for the first time it gives them recognition as an integral part of health care. Convalescent homes were formerly regarded as a rather luxurious appendage to the treatment of illness; they are now seen to be a necessity. Only about 40% of convalescent homes have been taken over and attached to boards of governors or management committees. Many have been left outside the Service, not because of inefficiency, but because of failure exactly to fulfil a statutory definition. Here again comes in the value of an organization

which is not frustrated by rigid official frontiers in the allocation of its help.

Other activities of the King's Fund are finding an increased scope. One of them is the Emergency Bed Service, established just before the war. This has become the agent of the four metropolitan regional boards for urgent admissions under the National Health Service. It was expected that its work might be doubled on the appointed day, actually it was quadrupled, but the organization took the strain and no disaster occurred. The Emergency Bed Service received a good deal of attention from the Press for political reasons, as being likely to illustrate the failures of the Act. Nevertheless, it has solid achievements to its credit, and the regional boards and the Ministry have given the fullest help and encouragement. Two other activities of the Fund, one in being and the other projected, are the setting up of a staff college for ward sisters, recently described in these columns (July 2, p. 30), and the coming inauguration of a catering centre at St Pancras Hospital to serve as a model in equipment and layout. In addition, bursaries are offered to assist the training of hospital administrators and almoners. The impression gained from this report is of an organization which is meeting new occasions with new duties. It is taking a broad view of the needs of hospitals helping in many ways where help is most needed, encouraging progressive hospitals, and introducing the human element, in which the best-laid State schemes are apt to be deficient

THE G.P. IN THE N.H.S.

The general practitioner who enters the National Health Service does so by making a contract with the local executive council. He is not an employee of the council, but a contractor with it, in the same way as his predecessor, the insurance practitioner, was in contract with the local insurance committee.

In England and Wales there are 138 executive councils, one for each county and county borough, except in eight cases where two areas have been combined under a single council. Each executive council consists of 24 members—four (with the chairman) appointed by the Minister of Health, eight appointed by the local health authority, seven doctors appointed by the local medical committee (which is elected by all the local doctors and is the successor of the Panel Committee) and three dentists and two pharmacists appointed respectively by their local committees.

The doctor newly starting in practice, like the established doctor who moves into a new district, can come into the Service anywhere in the country except in some areas declared to be over-doctored (see *Supplement* to the *British Medical Journal* of August 6, p. 70, and August 20, p. 93). An area may be closed to additional doctors and a vacant practice remain unfilled if it is considered that the area has more doctors than it needs. The control in this respect is exercised by a Medical Practices Committee, whose nine members, all appointed by the Minister, include seven doctors appointed after consultation with the British Medical Association, and five of the seven must be actively engaged in medical practice. To this Medical Practices Committee the executive councils report the number of doctors required to meet the needs of their areas and also any vacancies occurring in the Service. The committee can refuse a doctor's application to join the Service in a particular area only on one ground—namely, "that the number of medical practitioners undertaking to provide general medical services in the area or part of the area concerned is already adequate."

Formerly, vacancies in practices were commonly filled by purchase. The young doctor had to buy his way into general practice, starting perhaps as an assistant and presently buying either a practice of his own or a share in a partnership. This buying and selling of practices has been swept away so far as public practices—that is, practices within the National Health Service—are concerned, and a fund of £66,000,000 has been set up to compensate existing practitioners for the loss of the right to sell their practices, provided they entered the new service on or before July 5, 1948. This date may be extended in certain cases if the Amending Bill now before Parliament becomes law.

As vacancies in the Service can no longer be filled by purchase the M.P.C. may decide not to fill a vacancy; when a vacancy has to be filled the executive council will normally advertise it. A booklet entitled *The National Health Service* just issued by the Ministry states: "If only one doctor applies he will usually be given the practice automatically. If several apply, the executive council, when reporting their names to the committee, will add the opinion of the local medical committee and its own recommendations. Local ties and wishes, as well as local needs, will be taken into account. For instance, a partnership of doctors may want a particular man to join them, or a son may wish to carry on his father's practice. The doctor who fails to get what he wanted may ask the Minister to overrule the committee or to appoint him in addition to the doctor chosen by the committee."

The remuneration of general practitioners in the National Health Service is in general by capitation fee. The amount of the capitation fee has been the subject of long discussions, not yet terminated, between the Ministry and the British Medical Association. The maximum number of persons on the list of a single-handed doctor is fixed for the time being at 4,000. With the consent of the executive council after consultation with the local medical committee (or on appeal to the Minister) a doctor may have a fixed annual payment—a basic salary as it is called—of £300, plus capitation fees at a lower rate. This arrangement is intended to help doctors starting in practice. Normally the annual payment of £300 is subject to the condition that the doctor shall have a specified number of patients on his list within a given period of his entrance into the Service. There is also a fund amounting to £200,000 a year for extra payments to be made to doctors who practise in difficult or unpopular areas. In addition to the capitation fee there are certain extra payments such as for maternity services, for mileage in rural areas, and for dispensing. Doctors undertaking the training of a young assistant may also receive extra fees, and the Government scheme includes provision for superannuation, death benefits, and widows' pensions. Various public appointments, as well as, of course, private practice, are open to the practitioner.

A word about the disciplinary machinery. The executive council has no power to dismiss a doctor, but if after inquiry it feels that owing to a doctor's dereliction his contract ought to be cancelled the case is referred to an independent tribunal consisting of a lawyer-chairman appointed by the Lord Chancellor and a layman and a doctor both appointed by the Minister after consultation with the Association of Executive Councils in the one case and the doctors' professional organization in the other. If the decision of this tribunal is in favour of the doctor it is final; if it is against the doctor he has a right of appeal to the Minister, who, after careful inquiry and consultation with an advisory committee of doctors can override the tribunal in the doctor's favour.

An Advisory Bureau

With the changes which the National Health Service has brought about in the customary methods of entering upon practice, the Council of the British Medical Association felt the need of establishing some central machinery through which practitioners wishing to establish themselves in practice could obtain advice and information concerning suitable openings. The Medical Practices Advisory Bureau has been accordingly set up as a department of the Association at Tavistock Square. Its purpose is to advise all practitioners on individual problems connected with entry into, and conduct of, practice, and it includes an appointments information service through which the introduction of locumtenents, assistants, or partners can be effected. The Bureau is under the direction of one of the assistant secretaries of the Association (Dr. L. S. Potter), and it retains the services of some members of the staff of the British Medical Bureau, now in voluntary liquidation. Branch offices have been established at 33, Cross Street, Manchester, and at the Scottish office of the Association, 7, Drumsheugh Gardens, Edinburgh. It is hoped that in course of time other regional offices will play their part. The services of the Bureau are free of charge to members of the Association; others are expected to pay fees as a contribution to the expenses incurred.

A survey by the Medical Practices Committee in which the areas of England and Wales were scheduled according to doctor-need appeared in the *Supplement* of August 6 (p. 70) and of August 20 (p. 93).

THE PUBLIC HEALTH SERVICE

The public health service has been very greatly affected by the changes resulting from the National Health Service Act. The hospitals of local authorities, like the voluntary hospitals, have been transferred to the Regional Hospital Boards, and the public health service feels a natural disappointment at the loss of municipal beds. Moreover, maternity and child welfare services, instead of, as formerly, belonging to the smaller as well as the larger welfare authorities, are now included in the 150 county and county borough authorities which are the local health authorities under the Act. Tuberculosis officers, hitherto employed by local authorities, are now mainly officers of the Regional Boards. The number of chief posts in the public health service in relation to the total number in the service has always been small, and the Act has made them relatively fewer still, though a number of new types of post have been created.

At the moment of writing the long dispute between the British Medical Association and the associations of local authorities is ended, the associations having agreed, with a certain proviso, to participate in the Whitley machinery. It is to be hoped that the service will be so established that the best type of medical graduate will be attracted to make a career in public health, with prospects no less satisfactory than those which confront general practitioners and specialists.

The entrant into public health work usually begins as an assistant medical officer, doing maternity and child welfare or school work or both. Such medical officers are likely in future to specialize more directly either on the obstetric or on the child health side and to have opportunities of keeping up clinical knowledge by interchange arrangements with hospitals or by clinical assistantships, for which the D.P.H. is not essential. The Society of Medical Officers of Health has suggested that special experience in maternity or children's hospitals and the acquirement of some diploma such as the D.C.H. might in fact be more useful than the D.P.H. itself. But the Certificate in Public Health is regarded as the basic qualification for entrance into the public health service.

The L.C.C. Medical Service

Sir Allen Daley, Medical Officer of Health and School Medical Officer to the London County Council, kindly sends us the following: Whole-time appointments in the Public Health Department of the London County Council, apart from those of medical officer of health, deputy medical officer of health, and principal medical officer, include five senior medical officers, nine divisional medical officers, one principal assistant medical officer, six senior assistant medical officers, nine assistant divisional medical officers, and 67 assistant medical officers. Their duties are, in the higher grades, mainly administrative. The officers, speaking generally, have graduated through the clinical field and have special knowledge in at least one branch of the service. The assistant medical officers are mainly engaged in the school health and maternity and child welfare services. Suitable qualifications are the D.C.H. and the C.P.H. or the D.P.H. It is hoped that arrangements may be made for them to have clinical responsibilities at hospitals, and for some of them to gain experience of the environmental health services in the metropolitan boroughs.

For the grades assistant medical officer to senior or divisional medical officer the present salaries range from £910 to £1,800 per annum.

In addition the Council employs nearly 500 part-time medical officers in a variety of work—for example, in residential nurseries, welfare institutions, staff examinations, and sessional work at clinics and school medical inspections.

By arrangement with the London School of Hygiene and Tropical Medicine, the Institute of Child Health, and several undergraduate schools, students are given opportunities of gaining experience in the Council's various medical services.

Correspondence

The M.R.C.P.

SIR,—Dr. F. M. R. Walshe's admirable criticism (August 13, p. 383) of the tests of merit to be applied to men and women in the middle of a career is relevant to the testing of young persons on its threshold, so I venture to offer some comments on the College committee's report on the examination for M.R.C.P.

At present the career of medical "consultant" in England is virtually closed against all young people who have not passed this examination. In the year ending September 29, 1948, candidates, successful and unsuccessful, paid the College £33,873. In 1948 a candidate was under examination for approximately seven and a half hours, of which six were devoted to answering written questions, 70 minutes to the clinical examination, and 20 minutes to a pathology viva. In future the clinical examination will last 80 minutes. Those who have examined in the faculty of science of a university for degrees or diplomas valuable to would-be specialists (e.g., the London B.Sc. (Special) in statistics is a highly esteemed qualification for embryo statisticians) will notice that *their* examinees have a much longer run for their money. I use the sporting phrase because the College committee holds that if candidates found insufficient in the written examination were not admitted to the clinical examination they "might fairly complain of not having a run for their money." The system of marking was, and is to remain, such that if a candidate fails in his "long case" he will usually fail in the whole examination. The committee justifies this in the following passage:

> "The examination is meant to test method at least as much as knowledge; and if it puts a premium on readiness of judgment, that is defensible because this quality is useful to consultants. A former Censor has declared that, 'in the routine and method of examining a patient and in the recognition and evaluation of obvious physical signs, the candidate must be right first time.'"

"Obvious" is an ambiguous word: a professor of mathematics once said that "it is obvious that" in an examination script frequently meant "I cannot prove that." No doubt the committee would agree that many mental and moral qualities other than readiness of judgment are useful to consultants—forethought, caution, tact, sympathy. It is even arguable that readiness of judgment is of less importance to a young consultant, who will usually pass years in the service of a well-equipped institution where technical aids to diagnosis are available to him, than to a general practitioner in a remote country district who must depend wholly on himself. Perhaps the committee would retort that these other desirable qualities cannot be tested at all by examination. That might do less than justice to Censors. I should think that a wise physician who has the gift of putting a young man at his ease might in 20 minutes' talk learn a good deal about him. Not, of course, if he simply fired questions at him, but if he drew him out.

Is it possible—as a man with little clinical experience I am genuinely asking for information—that clumsy fingers and dull ears are now not the insuperable obstacle to success as a physician that they were 60 or 70 years ago? That now a man with a good brain, able to interpret the reports of technologists and the graphical records of machines, might be a very good physician although his fingers were clumsy, provided he had qualities not tested at all by the ritual of the "long case"?

What is, I suggest, probable is that the way to improve the examination, to make it do something more than put a premium on readiness of judgment, is to lengthen it. There are two ways of doing this—drastically to reduce the number of candidates and/or to increase the number of examiners. The committee declines to make the examination longer, but it does propose to increase the number of examiners and reduce the number of candidates. It is not clear from the report how many additional examiners are to be appointed, but they are not to be "elder statesmen." The candidates will be reduced

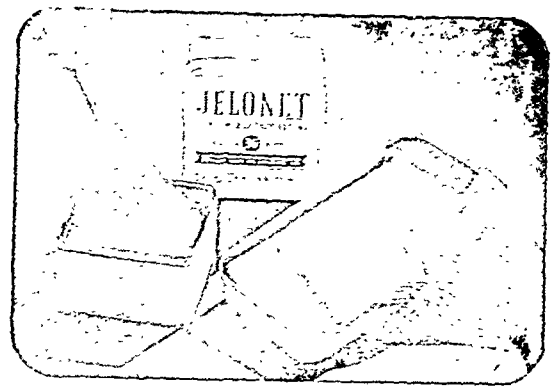
Suspension of Sulphathiazole—Boots

Whilst Sulphathiazole is the drug of choice in many infections, it is often difficult to persuade a sick child to take frequent doses of tablets. SUSPENSION OF SULPHATHIAZOLE — BOOTS is easy to administer — its pleasant taste and attractive colour appeal to children of all ages.

One fluid ounce of SUSPENSION OF SULPHATHIAZOLE — BOOTS contains two grammes of finely divided Sulphathiazole, B.P., in a pleasantly flavoured base.



Supplied in bottles of 6 fluid ounces and in bulk for dispensing purposes.

PRINCIPLES of NUTRITION

Increasing interest is now being shown in the principles of nutrition in relation to preventive medicine. If these principles become more fully appreciated by every individual responsible for planning meals, a well-balanced diet should be available to the whole community, thereby improving the general standard of health.

Because it provides vitamins of the B_2 complex, Marmite is a valuable protective food; it is specially indicated for expectant and nursing mothers, for children of all ages, and in cases where the diet is restricted.

MARMITE
yeast extract

contains
Riboflavin (vitamin B_2) 1.5 mg. per oz.
Niacin (nicotinic acid) 16.5 mg. per oz.

Jars: 1-oz. 8d., 2-oz. 1/1, 4-oz. 2/-, 8-oz. 3/3, 16-oz. 5/9

Obtainable from chemists and grocers

Special terms for packs for hospitals, welfare centres and schools

Guilty over-indulgence is rare in these days of rationing but, nevertheless, the stomach may easily be insulted without the condonation of its owner.

A great proportion of the present-day ration consists of carbohydrate and, as a result, hyperacidity is probably the commonest of all gastric disturbances. Unfortunately, nowadays, it is not easy to vary the diet so that in most cases relief must be sought by the use of a suitable corrective such as 'BISODOL.'

'BISODOL' is a very fine powder which enables the sedative and antacid effect of its Bismuth Subnitrate, Magnesium Carbonate and Sodium Bicarbonate to spread protectively over the mucosa.

The inclusion of diastase aids carbohydrate digestion, while the Ol. Menth. Pip. is a valuable carminative.

Cold Front

THE RELATION between changes in weather and the onset of colds has long been recognised. Recent surveys prove that a "cold front" is often followed by colds and sore throats. Chilling easily upsets nasal function so that the precept "keep warm" remains valid.

'ENDRINE,' in conjunction with general measures, will bring relief and help to avoid complications by allowing free drainage of purulent secretions.

Formula: ephedrine 0.75% *w/w*; menthol 0.5% *w/w*; camphor 0.5% *w/w*; eucalyptol 0.5% *w/w*; oleum ricini 0.35% *w/w*; light liquid paraffin q.s.

'ENDRINE' is available in three varieties: Ordinary (0.75% Ephedrine) Mild (0.5 % Ephedrine) and Isotonic (0.5 % Ephedrine Hydrochloride).

Why 'Ribena' in Skin Disorders?

Because the beneficial role of vitamin C in maintaining the integrity of the skin has been evidenced by the good results reported from its use in various skin disorders.

Notably, because excellent results are reported with natural vitamin C, in the form of 'Ribena' blackcurrant syrup in specific cases of skin disorder, for example acne rosacea, allergic skin manifestations, and even psoriasis. Cases of dry skin and flexual eczema, too, in a large group of school children cleared up rapidly when their dietary was supplemented with Ribena. More specific information will be gladly supplied on request.

Ribena is the pure undiluted juice of fresh ripe blackcurrants with sugar, in the form of a delicious syrup. Being freed from all cellular structure of the fruit, it will not upset the most delicate stomach. It is particularly rich in **natural** vitamin C (not less than 20 mgm. per fluid ounce) and associated factors.

by allowing no candidate to try his luck more than twice within a year. On the data available this would reduce the number sitting at each quarterly examination by about one-third. Still, even 380 is a good round number when one remembers that under the by-laws of the College "the four Censors bear entire responsibility for the results of the examination, and they should, therefore, continue to conduct, alone, the Final Viva."

A veteran of medical statistics will be forgiven if he expresses a little (not much) surprise that the committee did not use its very extensive statistical data roughly to verify its hypothesis that the examination does effectively test something, let us say readiness of judgment. Suppose one tabulated by candidatures—1st, 2nd, etc.—the proportion rejected, then, if the proportions were equal, the *prima facie* interpretation would be that chance ruled. If the proportion steadily increased, the *prima facie* interpretation would be that the test steadily weeded out the unsuitable candidates. I am too old a hand to suppose that this comparison would be decisive—many sub-tabulations would be required to justify either inference—but such an analysis would be rational and, I think, should have been made.

What the committee's reforms do is to make an examination of the present content controlled by the Censors slightly less onerous for the examiners. Like other intelligent people, the committee sees that the scope of the examination could not be increased without delegation of power. If the examinees were distributed through the medical faculties of the British universities having schools of clinical medicine, then the scope of the examination could be widened without putting intolerable pressure upon the examiners, but some people would ask why the ancient College should have a papal authority over it.—I am, etc.,

Loughton, Essex. MAJOR GREENWOOD.

Distinction Awards

SIR,—I was pleased to see that Dr. F. M. R. Walshe (August 13, p. 383) had written a characteristically forthright letter criticizing the crazy notion of distinction awards for consultants. As a Fellow of the Royal College of Physicians of London I might conceivably have felt it possible that my name would be among those being considered for one of the grades, but as I have refrained from joining the Service, and am therefore not eligible for any of the financial rewards, I can take a somewhat detached view.

From the beginning it was obvious to the meanest intelligence that mere volume of work made it quite impossible for the Awards Committee to accomplish their task. It now seems that they have decided to invite hospital medical committees and various other bodies to submit recommendations. They may report "confidentially" to the chairman of the Awards Committee. I like this word "confidentially." It sounds so much better than "secretly" and has less sinister associations.

Dr. Walshe points out the extreme difficulty of defining "distinction." Has the Awards Committee arrived at a satisfactory definition, and if so will they pass it on, and perhaps suggest a points system to cover the various questions asked by Dr. Walshe? If they do, there still seem to be insuperable difficulties in the path of each subcommittee. How much do we really know about the professional abilities even of our colleagues on the staff of the same hospital? We never see more than a minute fraction of their work. How often does a surgeon watch another surgeon operating, or one physician see another taking a history and examining a patient? Add to this the inescapable fact that personal friendships and jealousies are apt to cloud judgment, and it will surely be admitted that with the best will in the world and the strictest possible integrity no just grading can be accomplished.

Another difficulty I foresee is the position of the members of the various committees, including the Awards Committee. Will they begin by choosing themselves and each other or will a becoming modesty compel them to ignore their own claims? And what evidence is to be obtained about teachers? The best judges of them are unquestionably the students. Will the Awards Committee collect a random sample of students and ask them for a "confidential" report on their teachers?

When the holders of distinction awards die or retire, as Nature decrees that they must, the prospect is even more terrifying. Presumably there will have to be a series of by-elections to decide which of the hundreds of anxious candidates are to be elected to fill the vacancies. Surely the whole project is too fantastic to be seriously considered by a learned profession. But we must admit that it is a masterly example of the principle "Divide and rule," and it would be interesting to know who were the originators.—I am, etc.,

London, W.1. C. C. BEATTY.

SIR,—In his authoritative letter (August 13, p. 383) Dr. F. M. R. Walshe asks what constitutes "distinction" in medicine, and offers diverse answers to the question. He concludes that "there is no practical answer to these pertinent questions." His letter is matched by the bewilderment of all with whom I have discussed this problem. The Awards Committee may have an acceptable scheme of assessment in mind, but consultants may be forgiven for having grave doubts. May I put forward a scheme which has found favour with colleagues who have considered it?

First we must be clear what is to be done—and with what resources. In my letter in the *Supplement* of August 20 (p. 96) I suggested that 14% of the total basic salary paid to all consultants year by year represents the resources of the Awards Fund. This fund should be distributed so that provision is made: (1) for those holding awards to take extra sessions; (2) for promotion from grade to grade, and into a grade for those who receive no award initially; and (3) for the grading of junior consultants in the future. Assuming that the finance is on a satisfactory permanent basis the funds are to be distributed in certain proportions to those nominated by the Awards Committee appointed by the Minister of Health. I believe this could be done fairly and without any secret recommendations by local caucuses. About a million pounds a year is involved, and both the public and the profession may fairly claim to know how and on what grounds this public money is spent.

The idea of distinction may be divided simply into three sections: (1) Qualifications—professional and scientific. (2) Consultant service—appointments, seniority, offices of distinction in medical academic societies, and service as an examiner. (3) Publications—original and compilatory work. The following scheme is based upon this primary division. The marks

	Total Marking	Detail Marking (highest mark in each subsection counts—not additive)	
Section 1. Qualifications:			
Medical qualifications ..	18	F.R.C.P., M.R.C.P., F.R.C.S., etc.	18

Press Reports on Technical Subjects

SIR,—The May issue of the *Journal of General Microbiology* (p. 274) contained a highly technical paper of mine on "The Incidence of Penicillin-sensitive Variant Colonies in Penicillinase-producing Strains of *Staphylococcus pyogenes*." This recorded the fact that when kept under laboratory conditions for some length of time many strains of penicillinase-producing staphylococci give rise to a proportion of penicillin-sensitive variant colonies. While these experiments indicate that penicillin-destroying strains of staphylococci are genetically unstable in the test-tube, they cannot readily be interpreted in terms of penicillin-resistant infection.

An account of this paper and of my work which appeared in a national newspaper on August 9 implied that such an interpretation had been made. This is not the case. I should perhaps add that the writer of the article had not consulted me at any stage. This seems to me to raise an issue of some importance for all medical research workers. Is there no way by means of which they can be protected from this type of reporting of their work in the popular press? More important still, is there no way by means of which the general public can be protected from the false conclusions so presented to them?—I am, etc.,

London, S.E.1. MARY BARBER.

Treatment of Rodent Ulcer

SIR,—The tendency in treatment is that when a case is referred to a specialist it is treated according to his methods of therapy unless there are clear-cut reasons for other branches of therapy. To the plastic surgeon a rodent ulcer asks for surgical excision, and the more difficult the resulting area is to close the more fascinating the problem. To the radiotherapeutist *x* rays are the obvious answer. It is essential that any specialist should know what can be done by his colleagues in other specialties, and this can only be done by close co-operation.

For the past 18 months I have held a clinic with my radiotherapeutic colleague, Dr. F. Ellis, and we decide which form of therapy we think is most suitable for each particular case. In this early stage one cannot draw conclusions. In any form of treatment where two methods of treatment are available (and we must agree that in the majority of cases *x*-ray or surgical treatment gives equally good results) there must be at either end of the scale cases which are better treated by one or other form of therapy and others which may require a combination of the therapies. The difficulty is deciding which is best, and this can be done only by seeing the results of all forms of therapy.—I am, etc.,

London, E.1. CHARLES HEANLEY.

POINTS FROM LETTERS

Shunts in Essential Hypertension

Dr. RUDOLF LOVREC (Maribor, Yugoslavia) writes: I have read with interest Professor F. H. Smirk's paper on essential hypertension (May 7, p. 791) and should like to draw attention to the value of shunts from arterioles to veins. They cause more oxygen to be present in the veins, so that their intima receives the needed oxygen. All over the body there are such arteriovenous shunts—in the lungs, in the liver, in the kidneys, in the tips of the fingers and toes, and in the coccyx (glomerulus coccygeus). Vertebrates, as the dog and wolf, have in their tails such a glomerulus of much greater size. I think this phenomenon of arteriovenous shunts is of very great importance for the nourishment of the veins. When it is disturbed a condition of malnourishment of the intima of the veins arises. Such abnormal veins set free into the circulation a substance that causes the blood pressure to rise, in order that more oxygen may be obtained by the veins.

Syringes

Dr. H. MAITLAND MOIR (Currie, Midlothian) writes: I see Dr. T. G. Benjamin (July 30, p. 282) says that a stuck piston in a syringe results in a broken barrel. I had a stuck metal piston recently, and when all efforts had failed to free the piston I put it in my refrigerator for a few hours, after which the piston came away quite easily. It may not always work out that way, of course, but it is worth trying.

Obituary

SIR CRISP ENGLISH, K.C.M.G., F.R.C.S.

Sir Thomas Crisp English, who died on August 25 at the age of 71, was elected to the surgical staff of St. George's Hospital in 1904 on the untimely and unexpected death of Herbert Allingham.

The son of Dr. T. J. English, whose family was well known in the North Riding of Yorkshire, he was educated at Westminster School and St. George's Hospital, where he was a William Brown Scholar. He qualified in 1900. When he was surgical registrar in 1902 he won the Jacksonian Prize for his essay on head injuries, and for a time he toyed with the idea of specializing in this branch of surgery. But in 1901 Edward VII had been operated on for acute appendicitis by Sir Frederick Treves in dramatic circumstances on the eve of his coronation, and the public—lay and medical—became "appendix-minded" overnight as it were. English was one of the first to perceive the implications of this, and he set out deliberately to become pre-eminent in the surgery of this organ. How fully he achieved this ambition is common knowledge. His success was no fluke; it was thoroughly well deserved, for he was an extremely dexterous, careful, and conscientious surgeon. There must be thousands who can testify to his skill and kindness and his unremitting care. He also had the vision to foresee that asepsis was inevitably going to supersede antisepsis, and he adopted it whole-heartedly. He realized even in those days, however, that aseptic technique depended on a chain of essential precautions and that perfection could only be arrived at if each link in the chain was as strong as another. He took the most elaborate care to ensure this in his operating theatre, and his results showed how successful he was. As his experience grew, he began to discover for himself, what is now common knowledge, that appendicitis is a protean malady, that a disordered appendix can give rise to a number of symptoms which are not at first sight referable to the organ itself. But his immense success in private practice left him no time then to publish these observations, even if the urge to do so had been strong in him. The very greatness of his reputation for operations on the appendix had in one sense an unfortunate result. It tended to obscure the fact that he was also an extremely good general surgeon. To see him remove a breast for carcinoma, to take one instance, was an object lesson in how that operation should be done.

[*Russell, London*

In the 1914–18 war English was sent to the Middle East, and on his return he was made a C.M.G. in 1917 and advanced to K.C.M.G. in the following year for his distinguished services there. As consulting surgeon to the British Salonika force and the British Forces in Italy he was four times mentioned in dispatches, and was made a Knight-Commander of the Order of George I of Greece. He was also awarded Serbian and other decorations, and many other distinctions came his way. A Knight of Grace of the Order of St. John of Jerusalem, he was also a member

of the Chapter-General of the Order. Sir Crisp English was vice-president of the Section of Surgery when the B.M.A. met at Portsmouth in 1923. Later he represented his constituency at the Annual Representative Meetings in 1933–6, and again in 1938. He was a member of the Central Council from 1933–7, and at different times he gave valuable service to the Finance Committee, the Hospitals Committee, the Arrangements Committee, and the Parliamentary Elections Committee. He was also president of the Metropolitan Counties Branch of the B.M.A. in 1939–40. Apart from his long connexion with St. George's Hospital he served the Hospital of St. John and St. Elizabeth, Queen Charlotte's, and Beckenham Hospital, and he was also associated with the Royal National Orthopaedic Hospital and the Royal Hospital, Chelsea.

Between the wars his success was, if possible, greater than ever. Even so, he always found time to give to the interests of St. George's Hospital, for which he had a passionate and lifelong devotion. The suggestion that it should be moved from its present site was to him anathema. Whenever the idea was mooted, as it has often been during the last forty years, he fought it tooth and nail; and if he had lived to see Hyde Park Corner unadorned by the hospital, as one day soon it will be, he would have regarded the landscape with pain and grief and horror.

When he retired from the active staff of St. George's I wrote this of him—and I am going to repeat it now, because I can think of no better epitaph for him: "St. George stands for England and all that is English: English stood for St. George's and all that is St. George's."—I.B.

W. T. WARWICK, M.B., F.R.C.S.

Mr. William Turner Warwick, senior surgeon of the Middlesex Hospital, died there on August 21, at the age of 61.

He was born in 1888, educated at Doncaster Grammar School, and in 1906 entered Emmanuel College, Cambridge, where he studied mathematics and gained an honours degree. He was always deeply interested in education, and he left Cambridge to teach at Bedales School in 1909. While teaching there he worked for and won an entrance scholarship to the Middlesex Hospital in 1911. He took a remarkably short time to qualify M.R.C.S., L.R.C.P. in 1915, and after resident house appointments he joined the R.A.M.C. Three years later he returned in poor health, and although no one knew it he suffered considerably at times throughout his life. In 1918 he took the degrees of M.B., B.Ch., and, having already had time to become interested in rectal surgery, he gained the appointment of resident surgical officer at St. Mark's Hospital in 1919. There he obtained further practical experience which stood him in such good stead in future years. The next year, too, gave him valuable experience in general surgery at the Leeds General Infirmary as resident surgical officer. Working with Lord Moynihan and Mr. Littlewood he always regarded as of great importance, and he retained an interest in, and affection for, that hospital and his old associates.

Warwick had by this time become convinced that surgical treatment could only be based upon a sound knowledge of pathology, and in 1921 he returned to the Middlesex Hospital as surgical pathological registrar; by so doing he not only became a pathologist of unusual merit but inaugurated a close liaison between the laboratories and the surgical wards. In 1921 he married Joan, daughter of Theodore Harris, of Limpsfield, Surrey, whom he had first met during his teaching days at Bedales. He was appointed to the staff of the Middlesex Hospital in 1923 and became senior surgeon in 1945.

This brief recital can convey only a faint impression of the man he was. William Turner Warwick was a remarkable and complex personality. It was easy to underestimate him on early or superficial acquaintance, but the more one knew him the finer did he appear, and however well one did know him it did not seem possible to approach his depths. Among his outstanding characteristics were his kindness and understanding. No appeal for help would remain unanswered, and he had a way of identifying himself completely with the problems of others. He was always interested in the welfare of students and nurses, and gave them much practical assistance, although few realized this. He remained a true humanist, and intellectually he was a man of many and brilliant ideas. Few of these ideas he left in print. He became an authority on several subjects: on rectal surgery, on malignant disease in general, and particularly with regard to the correlation of the various methods of treatment. As one example his influence is most obvious in the pathology and treatment of varicose veins. In 1931 he published a short book, *The Rational Treatment of Varicose Veins and Varicocele*. Its importance was immediately appreciated and has been generously acknowledged by recent authors. In 1942 Warwick delivered a Hunterian oration on the growth of bone, and the views he put forward were original and stimulating though somewhat unorthodox.

On all subjects he carefully studied the work of others but never accepted unlikely statements or took facts for granted. His knowledge was vast, and there were few surgical problems that he had not considered. Warwick delighted in discussion, but would never advance his opinion without careful thought. His self-imposed standards were so high he could seldom believe a task was fully completed, and for this reason alone his writings were few in number. He was never facile of tongue, or vociferous concerning his ideas, and this may be regarded as unfortunate, but if he had been these things he would not have been the man so loved by all who knew him. As a surgeon he was very successful, and although there may have been better technicians few have obtained such consistently good results. This was often ascribed to "green fingers," but it was really a green and fertile mind which saw every case as a particular problem in itself, to be studied meticulously from all angles and to be followed with the greatest care in all its stages up to the final discharge. As a diagnostician he was superb, and he reached his conclusions by careful logical reasoning based on his wide and well-remembered experience. He demanded a "problem book" in which should be kept a record of all difficult cases with observations on where mistakes were made and how they might have been avoided. He preferred post-graduate teaching, and he would take immense pains in guiding his assistants. To work for him was always a privilege, and he was unfailingly tolerant and kind. If his ward rounds were not so popular with students as they might have been, it was because he did not care to talk over the conscious patient; on the other hand his operating sessions were a delight.

Towards his patients he was kindness itself and always found time to consider their feelings and their fears. His family, his wife, three sons, and a daughter, was the centre of his own life, and he never forgot that his patients also had their own homes and their relatives. He would never refuse a patient a chance, however remote, and would undertake long and fatiguing operations if there was the slightest hope of assisting the sufferer. Those who loved him in his completeness will always remember his acute sense of the ridiculous and his sudden "puckish" moods.

They will never forget those delightful shocks of surprise produced by his spontaneous shafts of penetrating and kindly wit. There are true rocks in this world, and he was one; so completely loyal and so entirely dependable. "T.W." was a great and an unusual man, and we are all much the poorer for his loss.

MAURICE NEWFIELD, M.R.C.S., L.M.S.S.A.

Dr. Maurice Newfield, who died on August 13 at his home in Great Bardfield, Essex, at the age of 55, was well known as a medical journalist. He was educated at the City of London School, and soon after leaving there he joined the Kensington Rifles, being subsequently commissioned and sent to Mesopotamia with the 3rd Battalion of the Bedfordshire Regiment. He was invalided to India, where he transferred to the Indian Army. He was then in charge of a signalling school until his return to England in 1919. As soon as he was demobilized he went abroad again to study at the Sorbonne and at Freiburg before becoming a student at Charing Cross Hospital, where he qualified in 1922 after a much shorter course than was usual even in those days. He held a number of resident posts at Charing Cross Hospital, and he was also for a time clinical assistant at the Hospital for Sick Children, Great Ormond Street. For a while he was in practice in Bloomsbury. Then in 1928 he was appointed a sub-editor on this *Journal*. He had already contributed an amusing brief medical section to the *Week-end Book* in 1924. It was while he was on the staff of the *Journal*, however, that he wrote *Parenthood: Design or Accident*, which is still popular and has sold over 200,000 copies. The pseudonym he used at that time was "Michael Fielding." This book had a preface by H. G. Wells, whom Maurice Newfield knew well. He spent a winter in Portugal with Wells, acting as his private physician. Another pseudonym that he used was "Richard Harley," but *Womanhood and Marriage* which he published over that name never had the same success as the "Michael Fielding" book.

Unhappily, in 1930 Newfield's health broke down, but he continued to do a great deal of work for the *Journal* even while he was a patient at the Mundesley Sanatorium. After this first breakdown he worked as a freelance from his own home until 1936, when he joined the staff of Butterworth's and assisted Sir Humphry Rolleston in editing the *British Encyclopaedia of Medical Practice*. In 1938 he went to the firm of Hamish Hamilton and set up the medical department there, and this he built up until it was recently taken over by another publisher.

During all his illnesses Maurice Newfield never stopped working. Even at Midhurst, where he underwent a three-stage thoracoplasty, he continued his many activities. There was no branch of medicine in which he was not interested and informed. In recent years he edited the *Eugenics Review*, and he was also keenly interested in the history of medicine. Maurice Newfield was a man of talent and personality and despite his poor health did valuable work as an author and journalist. His death will be deeply regretted by a wide circle of friends within and without the profession. He leaves a widow and one son, who is studying medicine.

Lord Horder writes: The death of Maurice Newfield at such an early age deprives medicine of one of its ablest writers, and many friends and colleagues of an example of courage and pertinacity in the face of ill-health which can hardly find an equal. This note of bravery is the dominant feature in Newfield's life. For twenty years the handicap of pulmonary tuberculosis pursued him, but even during the periods of active disease, and whilst in the sanatorium, his contributions to medical literature were never suspended for more than a few weeks. Newfield's published papers and books make a formidable list, but perhaps his best work was done as editor of the *Eugenics Review*. His monthly notes were boldly critical, but evinced very wide reading and a grasp of Galtonian principles unequalled by any of his contemporary writers. Newfield was a small man physically; was markedly unobtrusive; spoke with a low, soft voice, and to the general observer was not impressive. A quiet talk with him, however, discovered a mind out of all proportion to his physique, cultured and urbane, and leaving a lasting memory upon all who knew him. Once past this point there emerged a very lovable and very loyal friend.

Mr. Cedric Lane-Roberts writes: Of Maurice Newfield's indomitable courage and personal charm it is only possible to speak in eulogistic terms. Others will have told of his literary ability and his consummate editing capacity. Here nothing slipshod was ever countenanced, and with his easy and complete tact the erring sentence would be altered and moulded to his satisfaction and its final and obvious suitability and correctness. To see Maurice Newfield in the surroundings of his quite perfect family life was indeed a privilege. It was a genuine pleasure to hand him a book, asking for his opinion, and then to watch him while he deliberated before giving his verdict, fondling it all the while with the gentle hands of the true bibliophile. I used often to see him, his eyes burning with unquenchable vitality, sitting up in bed by the open window, by his side the telephone through which for months and months he had conducted his editing, his favourite books all around, ever an early copy of *Don Quixote* to hand, and nearest to him his Bible, his constant companion, which seemed to live when in his hands. He was widely read, and remembered what he had read—only one instance of his excellent memory. Anything selfish in word and deed were completely foreign to his nature, and to those who knew him quite inconceivable. This all made an unforgettable picture of a unique and beautiful character, fostered in family surroundings that so much helped to round off the whole. His host of friends will sympathize deeply with his widow and son in their tragic loss.

Dr. LEONARD CROSSLEY died in a nursing-home at Bradford-on-Avon on July 20, at the age of 80. After leaving Repton School he was at first attracted by industrial chemistry. Later he turned to medicine, and went to Edinburgh, graduating M.B., Ch.B. in 1900, and proceeding M.D. in 1903. From his boyhood at Arnside he maintained a lifelong interest in yachting. Always fond of music, he made this his other relaxation, and at Edinburgh, with a few other enthusiasts, he founded the Edinburgh University Musical Society. After qualifying, he took up tuberculosis work, and an appointment as the first medical superintendent of Benenden Sanatorium was followed by that of medical superintendent to Winsley Sanatorium, near Bath. Then he obtained the post of tuberculosis officer for Wiltshire, which he held until his retirement. In later years this appointment included heavy responsibilities in connexion with the county's orthopaedic scheme. Crossley stood out among his contemporaries, and subsequently he brought a wide culture and experience of life, with great clinical ability, to work which at first did not attract the best of the profession either in its conditions or its rewards. Practical common sense of a high order animated all he did, and his humorous neglect of the more useless and baffling departmental instructions is refreshing to recall. His official position was never as important as the fact that he was a friend of every doctor in the county. During his later working years he was handicapped by a most persistent and troublesome osteoarthritis of the hip, but never allowed the discomfort and limitations of this disability to change his sociable and friendly outlook on life. Crossley was chairman of the Trowbridge Division of the B.M.A. in 1927–8. He

resigned his appointment on reaching the age of 65, and enjoyed a peaceful retirement with his wife, taking an active interest in his garden and in the activities of his friends at Winsley. He was chairman of the Nursing Committee of the Bath and Wessex Children's Orthopaedic Hospital, and maintained his interest in the Trowbridge Voluntary Orthopaedic Clinic, being responsible for its financial administration. Leonard Crossley was a colleague truly loved by all, and he will be remembered by all who knew him.—J. B. L.

EPIDEMIOLOGICAL NOTES

Poliomyelitis

The numbers of notifications in the week ended August 20 were poliomyelitis 273 (236), polio-encephalitis 22 (18). Figures for the previous week are shown in parentheses.

Multiple cases (poliomyelitis and polio-encephalitis together) were reported from the following counties: London 35 (30), Bedfordshire 4 (2), Berkshire 11 (7), Buckingham 2 (2), Chester 6 (4), Cornwall 8 (6), Derby 9 (1), Devon 9 (9), Durham 2 (3), Essex 10 (19), Gloucester 5 (7), Hereford 2 (4), Hertford 3 (1), *Kent 6 (6), Lancaster 29 (23), Leicester 7 (4), Lincolnshire,* Lindsey 3 (1), Middlesex 13 (10), Norfolk 3 (3), Northants 6 (2), Northumberland 7 (4), Nottingham 10 (4), Oxford 2 (1), Somerset 5 (4), Southampton 11 (13), Stafford 6 (4), Surrey 7 (7), Sussex East 2 (5), Sussex West 3 (4), Warwick 4 (10), Wiltshire 4 (2), Yorks West Riding 50 (34), Flint 2 (0), Monmouth 2 (4).

Discussion of Table

In *England and Wales* there were increases in the notifications of whooping-cough 172, acute poliomyelitis 72, and dysentery 17. There were decreases in the incidence of scarlet fever 165, measles 457, and diphtheria 11.

The largest changes in the notifications of whooping-cough were an increase in Staffordshire 46 and a decrease in Warwickshire 33. The largest decrease in the notifications of measles was Warwickshire 160; the only large exception to the decreasing incidence was a rise of 54 in Glamorganshire.

The chief features of the returns for diphtheria were an increase in London 7 and decreases in Yorkshire West Riding 8 and Lancashire 5. No large variations were reported in the local trends of scarlet fever.

Of the 11 cases of typhoid fever 5 were notified in Lancashire, Bootle C.B. The chief centre of paratyphoid fever was Liverpool C.B. with 8 notifications. An outbreak of dysentery affecting 16 persons was notified in Durham, Hetton U.D. The only other large return of dysentery was Lancashire 12 (Liverpool C.B. 6).

Outbreaks of food poisoning occurred in Staffordshire, Wolverhampton C.B. 132, and Lancashire 206 (Warrington C.B. 144, Clitheroe M.B. 49).

In *Scotland* there were decreases in the notifications of dysentery 27, scarlet fever 24, measles 24, whooping-cough 14, and diphtheria 11. There were increases in the incidence of acute primary pneumonia 24 and acute poliomyelitis 9. The chief centres of poliomyelitis were Glasgow 7 and Fife County 5. The rise in the incidence of pneumonia was contributed by the western area.

In *Eire* notifications of measles were 48 fewer than in the preceding week. The 13 cases of paratyphoid were scattered throughout the country.

In *Northern Ireland* decreases were recorded in the notifications of measles 23 and whooping-cough 17, while a rise of 20 was reported for scarlet fever. The increased incidence of scarlet fever was due to the experience of Belfast C.B., where the cases notified rose from 15 to 36.

Week Ending August 20

Notifications of infectious diseases in England and Wales during the week included: scarlet fever 678, whooping-cough 1,637, diphtheria 59, measles 2,120, acute pneumonia 245, cerebrospinal fever 22, acute poliomyelitis 273, acute polio-encephalitis 22, dysentery 35, paratyphoid fever 30, typhoid fever 6.

Correction.—In the summary of Infectious Diseases and Vital Statistics No. 31, August 27, p. 491, the main column headings should read 1949 and 1948. They were misprinted as 1948 and 1947.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended August 13. [No. 32.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) Scotland. (d) Eire. (e) Northern Ireland. † Deaths recorded under each infectious disease, in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Rate per 1,000 total births (including stillborn)			33					31		

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

‖ Includes puerperal fever for England and Wales and Eire.

Medical News

New Minister of Health in Northern Ireland

Dame Dehra Parker, D.B.E., M.P., has been appointed Northern Ireland Minister of Health and Local Government in succession to the late Mr. William Grant, and she thus becomes the first woman Cabinet Minister in Northern Ireland.

Hebrew Medical Journal

The *Hebrew Medical Journal* enters its twenty-second year with the publication of Vol. 1 for 1949. This bilingual publication, edited by Dr. Moses Einhorn, comes from New York but maintains a close connexion with Israel in its endeavour to promote the development of Hebrew medical literature and terminology. The current issue includes a symposium on present-day public health problems in Israel (printed in both Hebrew and English), and contributions on old Hebrew manuscripts, the Bible and Medicine, and Hebrew medical terminology (printed in Hebrew only).

Study of Child Care

British advances in the field of child care are being studied by 45 doctors, nurses, and social workers from sixteen European and Middle East countries during a 15-weeks course in social paediatrics which has been financed by the United Nations International Children's Emergency Fund and organized by the Ministry of Health and the British Council. After a week in London for introductory lectures, the students are now working in small groups in centres at Birmingham, Bristol, Liverpool, Manchester, Newcastle, Edinburgh, and Glasgow. They will later return to London for final discussions and the study of various special services.

Register of Speech Therapists

The *Register of Speech Therapists* for 1949 has now been published, and medical practitioners can obtain a copy free on application to the registrar of the Board of Registration of Medical Auxiliaries, B.M.A. House, Tavistock Square, London, W.C.1.

Psychiatrist to Lecture in Australia

Professor Alexander Kennedy, Professor of Psychological Medicine in the University of Durham, has been invited by the Government of Victoria to advise it on mental health and psychiatric organization. The presentation to the Victorian Parliament of a new bill dealing with these subjects is being delayed until after his visit. Professor Kennedy will tour other States in Australia to lecture on mental health, under arrangements made by the British Council and the Australian Association of Psychiatrists.

Working Party to Investigate Fluorides

The Ministry of Education has announced that a Working Party has been set up to direct and organize an investigation on the prophylactic effect of the local application of a solution of fluorides to school-children's teeth. The members are as follows: R. Weaver, M.D., F.D.S., Ministry of Education (chairman); E. R. Bransby, Ph.D., Ministry of Health; Miss J. R. Forrest, L.D.S., Ministry of Health; W. G. Senior, O.B.E., Ph.D., F.D.S., Ministry of Health; G. J. Parfitt, M.R.C.S., L.R.C.P., L.D.S., Department of Preventive Dentistry, Eastman Clinic; B. R. Townend, F.D.S., West Riding Local Education Authority; W. Ritchie Young, F.D.S., London County Council; A. T. Wynne, M.D., Ch.B., B.D.S., L.D.S., Ministry of Education (secretary).

Wills

Sir Frederic Jeune Willans, K.C.V.O., Surgeon Apothecary to the King's Household at Sandringham, left £7,115. Dr. George Sandison Brock, of Jersey, left £17,712; Dr. Thomas Smith Duncan, of Nottingham, £19,370; and Dr. George Herbert Simpson, of Brighton, £16,022.

COMING EVENTS

Foot Inspection

The Foot Health Educational Bureau will hold a convention at the Caxton Hall, Westminster, on September 30, from 2.15–5 p.m., on "Foot Inspection in Childhood and Adolescence." The speakers include Dr. W. G. Booth and Mr. T. T. Stamm. Admission is free on presentation of a ticket, which may be obtained not later than September 15 from the Bureau at 121, Ebury Street, London, S.W.1.

American Course in Gastro-intestinal Surgery

The American National Gastroenterological Association announces that a course in gastro-intestinal surgery will be given at the Boston City Hospital, Boston, Mass., on October 27–29. It will be under the direction of Dr. Owen H. Wangensteen, Professor of Surgery, University of Minnesota Medical School, assisted by Lord Webb-Johnson. Enrolment is limited to 250. The fee will be $35. Information may be obtained from the National Gastroenterological Association, Dept. GSJ, 1819, Broadway, New York, 23, N.Y., U.S.A.

SOCIETIES AND LECTURES

Tuesday

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At Anatomy Lecture Theatre, Edinburgh University, September 6, 4.30 p.m., *"Synovial Membrane in Health and Disease,"* by Professor D. V. Davies.

APPOINTMENTS

CARLISLE, W. H., M.B., M.Sc., D.R.C.O.G., F.R.C.S.Ed., Consulting Surgeon, North Cambridgeshire Hospital, Wisbech, Cambs.

TAYLOR, D. WILSON, M.B., Ch.B., Consulting Ophthalmologist, North Cambridgeshire Hospital and Clarkson Hospital, Wisbech, Cambs.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Jones.—On August 14, 1949, at St. Mary Islington Hospital, London, to Erica (née Axelrad) and Dr. Alun Howard Jones, a son.

Nabarro.—On August 26, 1949, at University College Hospital, to Joan (née Cockrell), wife of J. D. N. Nabarro, M.D., M.R.C.P., a son—David.

Petit.—On August 19, 1949, at the Lady Chancellor Nursing Home, Salisbury, Southern Rhodesia, to Joan (née Lamplugh), M.B., Ch.B., D.T.M.&H., wife of Joseph Petit, a daughter.

Pridie.—On August 24, 1949, to Joanna (née Egerton) and Kenneth Pridie, F.R.C.S., of 58, St. John's Road, Bristol, 8, a son—William Ralcigh.

MARRIAGE

Sloan—Logan.—On August 27, 1949, at Glasgow, Flying-Officer J. Burnley Sloan to Mairi Buchanan Logan, A.M.I.A.

DEATHS

Belbin.—On August 22, 1949, at Hove Hospital, Harry Ashley Belbin, L.S.A., late of Cradley Heath and Rottingdean.

Blaber.—On August 21, 1949, at Farthings, Borough Marsh, Twyford, Berks, Percy Leonard Blaber, M.R.C.S., L.R.C.P., of Boat House, Marlow, Bucks, aged 77.

Cairns.—On August 23, 1949, at 36, Bankfield Lane, Southport, Lawson Miller Cairns, M.D.

Duffy.—On August 23, 1949, at 12, Glodwick, Oldham, James Joseph Duffy, M.B., B.Ch.

English.—On August 25, 1949, at Chilton Hall, Sudbury, Suffolk, Sir Thomas Crisp English, K.C.M.G., F.R.C.S.

Ferguson.—On August 27, 1949, at St. Helier Hospital, James Ferguson, C.B.E., M.B., B.Ch., of Cranleigh, Ashley Drive, Walton-on-Thames.

Gibson.—On August 19, 1949, at Lancaster, James Andrew Gibson, M.D.

Hopkins.—On August 21, 1949, at Croydon, Walter Kempson Hopkins, O.B.E., M.R.C.S., L.R.C.P., Surgeon-Commander R.N., Ret., aged 79.

MacRobert.—On August 24, 1949, at Edinburgh, Peter Carmichael MacRobert, M.B., C.M., aged 79.

Mortlock-Brown.—On August 20, 1949, Constance Anderson Mortlock-Brown, L.M.S.S.A., of Boode, Braunton, Devon.

Ross.—On August 25, 1949, at Ardrannich, Inveraray, Argyll, Donald Ross, M.B.E., T.D., M.B., Ch.B.

Shave.—On August 22, 1949, Edward Simpson Shave, M.R.C.S., L.R.C.P., F.R.C.V.S., of Bexhill-on-Sea, Sussex, aged 93.

Welply.—On August 24, 1949, at Rosemont, Thurgarton, Nottingham, George Chinnery Welply, M.B., B.Ch., late of Forest Gate, London.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY SEPTEMBER 3 1949

Correspondence

Freedom of the Citizen

SIR,—There is a more disturbing aspect about the method of deciding which Territorial officers should be embodied that your correspondents, "Lieut.-Col., R.A.M.C." (*Supplement*, July 16, p. 51) and "Not to be Embodied" (August 20, p. 98), do not mention. Perhaps they are not aware of it. The Ministry of Health is asking local executive councils to make this decision. These councils may, but are not forced to, consult the local medical committee. Our professional degradation is such that, after being trusted in two wars to manage our own recruiting and, I think, having justified that trust, the still existing medical machinery is being by-passed. In fairness to the public, the profession, and to individuals local medical committees must not operate any procedure that has been initiated by the Ministry of Health without negotiation with the profession.

It is possible that in the case of your two correspondents their local medical committees by their veto are simply registering their dissatisfaction with what is happening. That is an understandable though, I believe, a mistaken action.—I am, etc.,

Wolverhampton. ROBERT S. V. MARSHALL.

*** The Secretary of the Association writes: The Ministry has been informed that it would have been appropriate for prior consultation to have taken place with the Association before this circular was issued. We are awaiting the Ministry's reply.

A Medical Trade Union

SIR,—Dr. B. S. Alderson (*Supplement*, August 20, p. 98) urges on behalf of the Consett Division that "the profession should make a very earnest attempt to co-ordinate the action of all doctors." The Division suggests the introduction of a fighting fund; subscribers to forfeit their subscriptions if they fail to adhere to the policy adopted by majority vote. While I agree with the necessity for co-ordinated action by the profession, I do not believe that the solution is by a fighting fund. Defence trusts, medical guilds, fighting funds—call them what you will—are powerless to settle the problem of achieving united action unless they have statutory authority and legal power behind them.

I submit, Sir, that the solution is the immediate formation of a trade union. It is essential that the members of the profession be educated to the advantages of their joining a trade union recognized by, and affiliated to, the Trades Union Congress. In a letter from Dr. J. A. Gorsky (*Supplement*, April 16, p. 235) the whole position of trade unionism as it concerns the medical profession was lucidly explained. This letter appears to have aroused little or no comment. I suggest that it merits the close study of the Consett Division, and of all Divisions concerned with this vital problem. Dr. Gorsky gives the aims of trade unionism as defined by the Webbs: "A trade union as we understand the term is a continuous association of wage-earners for the purpose of maintaining or improving the conditions of their employment. The purpose of the trade union is the protection of the standard of life—that is to say, the organized resistance to any innovation likely to tend to the degradation of the wage-earners." Dr. Gorsky goes on to say: "Trade unionism should encourage a community of interest between employer and employee, even if the employer is the State and the employee the doctor. Unless we possess legal powers analogous to those of a trade union, both as regards withdrawal of service and the economic support which would be essential if that service is withdrawn, and we are afforded the full protection of the Trades Disputes Act, 1906, we are rendered materially impotent in our negotiations with the Government."

This is the answer to the problem posed by the Consett Division. The sooner we rid ourselves of the idea that trade unions are organized primarily for the benefit of one type of worker, or one particular political party, the better. It is time that we acknowledged that we, too, are workers, or wage-earners, in the full sense of the word. Let us organize ourselves accordingly.—I am, etc.,

London, W.6. B. ROSEFIELD.

Fifty-five Committees

SIR,—I have just been reading the *Supplement* of August 20 in which is given the lay-out of fifty-five committees of the B.M.A. which will take a hand in the management of the nation's health. It is incredible that any of us ever lived for more than a few weeks up to July 5, 1948, and more incredible still that the span of life lengthened as the years swept by. I feel much alarmed about what will happen to us now that the B.M.A. has become a department of State Health and formed its fifty-five committees. Fifty-five committees determined to do their stuff should produce something, if only they produce chaos and make the profession's life a misery—they will certainly not produce health.

I was once told of a place in the Cascara Mountains where the inhabitants were so healthy that a centenarian had to be killed in order to start a cemetery: history didn't say how many if any committees were formed to put over the cemetery idea or to kill the old man. Pity!

With the already established State committees plus fifty-five B.M.A. committees I feel that we should complete the plan and form a fifty-sixth to arrange for the abolition of cemeteries and a fifty-seventh to co-ordinate the workings of the fifty-six.

The Englishman is notorious or famous for his sense of humour and being able to laugh at himself; the medical profession—particularly the naturally established specialist and consultant—now has the greatest opportunity for proving this mooted characteristic to be a fact. I regret to say that I have never seen anything funny in what has happened and is happening to both doctor and patient, but I fell off my chair with laughter over the Parliamentary Elections Committee of the B.M.A.—I am, etc.,

St. Osyth. R. E. CLARKE.

Qualifications of Specialists

SIR,—Allow me to endorse the views expressed by your correspondent "Sic Vos Non Vobis" (*Supplement*, August 20, p. 96). At the same time I think there should be an intermediate grade—that of junior consultant—for those who, having spent many years in a specialty, have the experience but who may not possess the prescribed qualifications or senior appointment. We are all familiar with people who only "shine" at examinations!—I am, etc.,

Leeds. D. A. HERD.

Grading of Hospital Staff

SIR,—The grading of specialists has produced an amount of indignation and resentment, and this i applied should be enough to sweep away the wh which is professionally impossible and often insu

the specialists, like wounded Caesar, quite ready to defend themselves against Cassius and his like, find their arm nerveless when they discern that it is Brutus who wields the fatal dagger. However, a lot of water has flowed down the Tiber since Caesar's time and we should not be so readily overwhelmed. There will always be a Brutus, and some of us consider that he has been rather overactive in our affairs of late.

The remedy is simple : "For Brutus is an honourable man." *All that is needed is that we should regard our fellow men* as fully adult. Fortunately it is not necessary, or even desirable, to believe this to be true ; *it is sufficient to accept it as a good* working rule. We do not need nursery governesses and schoolmasters, with their itch to take our affairs out of our poor fumbling hands, and their stern judgments, punishments, and awards from which there is no appeal.

We do need a medical Bill of Rights so that no man shall sit in judgment on his colleagues who have committed no crime without their individual desire and consent. We also have a duty to see that in certification and reports there is appeal to a final authority whose income and tenure are not under the control of either party to the dispute.—I am, etc.,

Stone, Staffordshire. B. R. SWORN.

Discount on Drugs

SIR,—Prior to the introduction of the National Health Service the wholesale drug houses gave the dispensing doctor a discount of 10% but gave the chemist 30%. The explanation given for this favoured treatment was that the chemist had to make his living out of his sales. The chemist now not only gets a dispensing fee for each item but also is able to buy drugs at a lower price than the value of the prescription as costed by the pricing bureau and hence now makes two profits.

The Minister has set his face against providing private patients with free medicines, and if doctors are to retain any private patients during this time of increasing economic stress it can only be by keeping down the private fees. This in turn can only be achieved if the dispensing doctor can buy drugs at a cheaper rate than exists at the moment.

There can now be no justification for not extending the 30% discount to doctors, and I hope the contents of this letter will be brought before the wholesale drug trade for their immediate consideration.—I am, etc.,

Upminster, Essex. E. ANTHONY.

*** The Secretary of the Association writes : The General Medical Services Committee is discussing this point with the trade.

The Maternity Service

SIR,—I suppose everyone agrees with the object of the circular recently distributed by the Central Health Services Council (*Supplement*, August 6, p. 74). It is obvious that the quality and quantity of midwives will fall if in future the midwife is seldom more than a doctor's assistant. Something probably will have to be done to preserve the status and numbers of midwives, but in the meantime one can hardly defy the facts by sending round circulars stressing the Minister's hopes and intentions in this direction.

Actually, when the Minister sponsored the N.H.S. Act he hoped and intended that it would make a doctor available to every man, woman, and child in consideration of compulsory contributions. Full maternity services were included. In fact every service rendered by the medical practitioner was to become a statutory right of every citizen, and, moreover, the patient retained the right to decide his or her own requirements. In the past doctors have generally been ready to attend women in labour, and many of them believed that their technical assistance was an advantage to the patient. Most intelligent women believe this, too, and usually derive much comfort and confidence from the presence of a doctor during labour and the early days of the puerperium. Their example, especially when seen in high places, will probably have greater influence than administrative precepts. The fact that many women did not appreciate or could not afford medical services in the past is no reason why they should not enjoy them in future.

No doubt the way everyone has flocked to use the health services has presented the Minister with some difficult problems, but they cannot be solved by trying to convince people that a service that doctors provided for anything from five to fifty guineas is now not even worth having as a gift.

When a patient books a doctor for her confinement she is often far more anxious to secure his services in labour than anything else. Indeed, many women still do not appreciate the relative value of antenatal care at all and would not bother to consult a doctor for the two antenatal and one post-natal services specified by the Minister. While patients have free choice of doctor they will encourage the doctor who is prepared to be there when he is wanted, irrespective of anybody's views on whether it is technically necessary. I must admit I never have attended the confinement of a Cabinet Minister's wife, but I know that those for whom I am responsible appreciate my insistence upon the management of my own cases. I and my patients at any rate seem to have been brought up to believe that it is part of my job, and, whether I am paid for it or not, I shall go on doing it.—I am, etc.,

Eye, Suffolk. J. SHACKLETON BAILEY.

*** The Secretary of the Association writes: The General Medical Services Committee has dissociated itself from the contents of this circular and has asked the Ministry of Health to receive a deputation on the subject.

His Own Doctor

SIR,—I should like to support Dr. A. D. Belilios's letter (*Supplement*, July 30, p. 68) in which he claims that doctors should have the right to prescribe for themselves. If any *notice is taken of the Minister's ruling it will be particularly* unfair to the doctor practising in an isolated village, for it will mean that he alone of all the village is denied the benefits of the Health Service, while still being obliged to pay for it in stamps and taxation. It will also be unfair to the man who knows that his own treatment is the best available in the district (and in spite of this Government's exaltation of mediocrity for its own sake there must usually be a best). Is he to be compelled to accept second best or pay for his medicines ? This seems very far removed from the Minister's rosy promises.

Even apart from these two special cases it will be unfair to all general practitioners. For who will be so inconsiderate as to trouble a colleague with a burden he is well able to bear himself ? Even if he is too ill to treat himself the G.P. will rely on his locum or partner just as all his other patients will.

If we are to be denied the benefits of the N.H.S. we must demand to be excused any financial contribution towards it. The B.M.A. should also take legal advice as to whether the Minister is empowered to deprive any citizen of his right of medical attention. Failing this we must resort to trickery—reluctantly, but consoling our consciences with the thought that our line of action is at least less underhanded than the Minister's attempt to get something for nothing. Let us make arrangements to go on a colleague's list, but to act as his deputy for purposes of treatment. Then instead of signing our prescriptions "John Doe," we sign "John Doe, p.p. Richard *Roe*," and get our medicine just the same. In conclusion I should like to ask the Minister whether he believes that we as a profession are dishonest, or only as hypochondriacal as he is trying to make the rest of the populace.—I am, etc.,

Silver End, Essex. J. W. NICHOLAS.

Domiciliary Midwifery Service

SIR,—In his letter concerning the domiciliary midwifery service (*Supplement*, August 20, p. 98) Dr. Clement W. Walker has again drawn attention to the fact that a large section of the Royal College of Obstetricians and Gynaecologists undoubtedly do consider that a general practitioner should not be permitted to practise midwifery.

It is pertinent to inquire, in view of this opinion, why it is that in these days of an ever-expanding syllabus in medical educa-

that by increasing the dose a rapid cure is obtained in a greater percentage of cases, but that the incidence of unsatisfactory response is uninfluenced.

3. *Combined Use of Sulphamezathine Orally and Penicillin Locally (40 Cases).*—A series of 30 cases were treated with sulphamezathine orally in the smaller dose combined with penicillin drops 10,000 units per ml., initially instilled at one-minute intervals for 30 minutes. A further 10 cases were treated with the larger dose of sulphamezathine and the same mode of penicillin locally. As can be seen from Table III, in both these small series the percentage of cases with rapid response was high (29 out of 40). For this series of 40 cases as a whole, the proportion of unsatisfactory responses is, however, once more not diminished. This is clearly so for the 30 cases treated with the smaller dose of sulphamezathine, whilst the 10 cases treated with the larger dose of sulphamezathine in combination with penicillin are too few to allow any definite conclusions to be drawn.

4. *Sulphamerazine Orally in an Initial Dose of 0.5 g. and a Maintenance Dose of 0.25 g. at Eight-hourly Intervals (24 Cases).*—A series of 24 cases so treated, no fewer than 21 responded within one to three days, and the remaining three all cleared up within four to eight days, so that there was no case with an unsatisfactory response or relapse. Sulphamerazine had the further advantage that in none of these 24 cases was there any suggestion of intolerance, and the occasional cyanosis observed with sulphamezathine was entirely lacking.

TABLE II.—*...ive Results with Two Different Dosages of Sulphamezathine*

Dose		Total Cases	Clinical Cure in		Unsatisfactory Response or Relapse
Initial	Maintenance		1-3 Days	4-8 Days	
0·25 g.	0·125 g. 4-hourly	84	39·3%	44·0%	16·7%
0·5 g.	0·25 g. 6-hourly	57	68·4%	14·0%	17·6%

5. *The Series as a Whole.*—Table IV brings out the salient features observed with the different modes of treatment in this series of 151 cases compared with the previously recorded result. If the small series of 24 cases treated by sulphamerazine is excluded it would seem that the methods recorded in the present study have failed to reduce the incidence of unsatisfactory responses and relapses. It is, however, clear that two conclusions can be confidently drawn regarding the use of penicillin and the sulphonamides. First, the intensive use of penicillin locally at one-minute intervals is still the best mode of applying

TABLE III.—*Results Obtained by the Combined Use of Sulphamezathine Orally and Penicillin Locally*

Mode of Treatment		Total No. of Cases	Cases Showing Clinical Cure in		Cases Showing Unsatisfactory Response
			1-3 Days	4-8 Days

(*a*) 0·25 g. *initial dose*; 0·12 g. maintenance dose, 4-hourly		30	20	1	9
(*b*) 0·5 g. initial dose; 0·25 g. maintenance dose, 6-hourly	" "	10	9	1	0

TABLE IV.—*Salient Features in the Present Series Set Against Main Results Previously Recorded*

	Total No. of Cases	Percentage of Cases Showing	
		Clinical Cure in 1–3 Days	Poor Responses or Relapses
Previous series:			
Sulphanilamide, sulphapyridine, sulphathiazole, sulphadiazine, or sulphamerazine orally (2·5 g. initially and 0·125 g. 4-hourly)	333	32·4	16·3
Penicillin locally	104	74·0	26·0
Penicillin intramuscularly and orally	39	84·4	15·6
Present series:			
Penicillin systemically (800,000 units)	4	0·0	100·0
Penicillin intramuscularly and orally	26	57·7	42·3
Sulphamezathine: 0·5 g. initially and 0·25 g. 6-hourly	57	68·4	17·6
Sulphamezathine: 0·25 g. initially and 0·125 g. 4-hourly, with penicillin locally	30	66·6	30·0
Sulphamezathine: 0·5 g. initially and 0·25 g. 6-hourly, with penicillin locally	10	90·0	0·0
Sulphamerazine: 0·5 g. initially and 0·25 g. 8-hourly	24	87·5	0·0

penicillin in ophthalmia neonatorum. Secondly, the sulphonamides can with advantage be used in higher doses than those employed at present. A more rapid response is obtained if an initial dose of 0.5 g. is given, with a maintenance dose of 0.25 g. at six-hourly intervals with sulphamezathine and at eight-hourly intervals with sulphamerazine. As to the small series with sulphamerazine, the suggestion is that this drug may prove the sulphonamide of choice, possibly reducing the frequency of unsatisfactory responses and relapses as well as giving a high incidence of rapid results. The chance occurrence of a high proportion of these 24 cases being due to organisms readily susceptible to sulphonamides cannot, however, be excluded.

Therapeutic Failures

In the present series of 151 cases there were 34 which gave an unsatisfactory response or which relapsed; 15 of these were observed in the 30 cases treated with penicillin intramuscularly or orally. As this method of treatment was experimental and has proved unsatisfactory, these 15 cases need not be considered in any detail. It is enough to note that they did not contain an undue proportion of relatively resistant organisms.

Of the 121 cases treated by sulphamerazine or sulphamezathine with or without local penicillin 19 gave a poor response or relapsed. These 19 cases were observed in a series of 87 cases—the 57 treated by large doses of sulphamezathine orally and the 30 treated by sulphamezathine in smaller doses with penicillin locally. Seventeen of these 19 were relapses; in one case—completely negative bacteriologically—there was a persistent membranous cast of the conjunctiva, and in the remaining case diphtheroids, coliform bacteria, and inclusion bodies were present, leading to prolonged treatment but ending in a primary cure. Table V shows the clinical features of these 19 cases in comparison with the cases responding satisfactorily. It is clear that unsatisfactory response is not related to degree of severity of the affection.

TABLE V.—*Degree of Severity in Cases with Satisfactory Response Compared with that seen in Cases with Relapse*

	Whole Series (121 Cases)	Series of 87 Cases	17 Cases with Relapse and 2 Cases with Slow Response
Mild	40	31	4
Moderate	62	41	10
Severe	19	15	5

Table VI sets out the data concerning cause [illegible] It will be seen that the cases with unsatisfactory response are not confined to any one aetiological group. In all groups the satisfactory responses considerably outnumber the cases with relapse or slow response. It should, however, be noted that 10 out of the 19 cases showed inclusion bodies either alone or in combination with organisms. In the whole series of 121 cases inclusion bodies occurred either alone or in combination with organisms in 33 cases. There are therefore 10 failures out of 33 cases showing inclusion bodies, and nine failures in 88 cases without inclusion bodies. This confirms the previously recorded observation that cases with inclusion bodies are the most resistant to treatment. As the difficulty centres on relapse rather than on slow response, the question arises whether such cases should not be given a longer consolidation treatment than cases of ophthalmia neonatorum due to other exciting organisms.

TABLE VI.—*Distribution of Organisms in Cases with Satisfactory Response Compared with that seen in Cases with Relapse or Slow Response*

Discussion

The present study suggests that the sulphonamides, used in larger doses than those advocated until now, tend to give results almost as rapid as those obtained by the intensive local use of penicillin. With larger doses of sulphonamides some 60 to 70% of cases of ophthalmia neonatorum give a clinical cure within one to three days. This is still less rapid than the results obtained with intensive local penicillin treatment, but not to any marked degree. Local penicillin therapy has the advantage that it can suppress pus formation within 20–30 minutes, whereas the sulphonamides take the better part of 24 hours to achieve this initial improvement. Sulphonamide therapy is, however, much simpler in application and is far less exacting on both the baby and the nurse.

When sulphonamides were first used in the treatment of ophthalmia neonatorum a dose of 0.125 g. initially and 0.062 g. at six-hourly intervals was given (Sorsby, Hoffa, and Smellie, 1942). Subsequently the maintenance dose was raised to 0.083 g. With these doses the incidence of unsatisfactory response and relapse was 38.1%. With the subsequent increase of the dose to 0.25 g. initially and 0.125 g. as a maintenance dose at four-hourly intervals this percentage fell to 16.3.

The higher dose suggested in the present study, whilst not influencing the relapse rate, has the merit of reducing the duration of treatment. This higher dose is innocuous and there is nothing to be gained by not adopting it as the standard dose for ophthalmia neonatorum. As between

TABLE II sulphamerazine, the advantage seems ierazine, though it has still to be proved y of relapses with this drug will be less sulphamezathine. Contrary to expectation, the combined use of penicillin locally and sulphonamide orally does not seem to reduce the relapse rate, but it should always be borne in mind that relapses are sometimes, possibly often, reinfections rather than relapses in the true sense.

Routine Procedure for Treatment

The steps in the two alternative methods of treating ophthalmia neonatorum available at present—sulphonamides orally and penicillin locally—may be thus summarized:

(*a*) *Steps in Common for the Two Methods.*—On admission a swab is taken for smear and culture and the eye is irrigated with half-normal saline at room temperature. A drop of adrenaline 1 in 1,000 is instilled and a scraping is taken from the palpebral conjunctiva for examination for the presence of inclusion bodies. Gutt. atropinae sulphas, 1%, are instilled if the cornea is affected. Any pus that may have accumulated is wiped away with moist pledgets of cotton-wool.

(*b*) *Procedure for Sulphonamide Treatment.*—(1) After the preliminary measures a tablet of sulphamerazine or sulphamezathine (0.5 g.) crushed into powder is given by mouth in a teaspoonful of water or milk. Alternatively a stock mixture can be used. (2) Sulphamerazine administration in doses of 0.25 g. is continued every eight hours. If sulphamezathine is used the administration has to be at six-hourly intervals. (3) Local treatment consists of three-hourly irrigation with saline solution during the first day in cases with profuse discharge; as a rule there is no need for further irrigation on the subsequent days. After irrigation medicinal paraffin is instilled as a precaution against the sticking together of the lids. (4) Atropine is instilled three times daily in cases with corneal haze or ulceration. (5) Sulphonamide administration is continued for 48 hours after clinical cure.

With this treatment swelling of the lids generally subsides within 12 hours after admission; purulent discharge disappears within 24 hours.

(*c*) *Procedure with Local Penicillin Therapy.*—(1) The preliminary measures are completed by the instillation of a drop of penicillin in a concentration of 10,000 units per ml. into the conjunctival sac. (2) The baby is now placed on the nurse's lap, while another nurse sitting near by instils one drop of penicillin solution, 10,000 units per ml., every minute for 30 minutes. Irrigation is not needed, as pus does not form to any extent; such thin mucoid discharge as is present can be ignored or, if it clings to the lid margin, wiped away with moist pledgets of cotton-wool. (3) At the end of this time there is invariably no pus and generally little or no discharge. The eye, however, is still moist, the lids are still swollen, and the lid margins tend to be sticky. The baby is returned to its cot, and instillation of penicillin drops is continued six times at five-minute intervals, followed by a similar number of instillations at half-hourly, hourly, and two-hourly intervals. This gives a total of 22 hours' treatment. Many cases require no further attention. (4) In some babies the lid margins still tend to remain sticky. It is advisable in such cases to continue with penicillin at two-hourly intervals until the eye is dry, when treatment is carried on for a further 12 hours.

Crystalline penicillin only should be used for making up the drops. Impure penicillin is likely to cause irritative reactions.

Summary

A series of 151 cases of ophthalmia neonatorum treated by several different methods is recorded.

Oral administration of doses of 200,000 units of penicillin, either exclusively or after an initial intramuscular injection, has proved disappointing.

Combined oral sulphonamide and local penicillin therapy proved effective in reducing the duration of treatment but ineffective in reducing the considerable frequency of relapses seen with either sulphonamide or penicillin therapy.

Duration of treatment was likewise reduced by increasing the dose of sulphonamide. With sulphamezathine, 0.5 g. initially and a maintenance dose of 0.25 g. six-hourly, some 70% of cases showed clinical cure within one to three days. Similar results were obtained with sulphamerazine, 0.5 g. initially and 0.25 g. at eight-hourly intervals. The use of these larger doses of sulphonamide does not apparently influence the relapse rate; it is, however, possible that sulphamerazine may prove to be a favourable exception.

For the present the best way of administering penicillin is still the instillation of drops of 10,000 units per ml. initially at intervals of a minute for half an hour and subsequently at less frequent intervals. For the best results with sulphonamide therapy higher doses than those used previously are necessary.

We are indebted to the matron of White Oak Hospital and Sister Condon, of the Ophthalmia Neonatorum Unit, for their loyal help in the treatment of the cases recorded here.

BACTERIOPHAGE TYPES IN PENICILLIN-RESISTANT STAPHYLOCOCCAL INFECTION

BY

MARY BARBER, M.D., B.S.

AND

J. E. M. WHITEHEAD, M.A., M.B., B.Chir.

(From the Department of Bacteriology, St. Thomas's Hospital Medical School)

Many studies concerning the incidence of penicillin-resistant staphylococcal infection have been reported, and it is now generally agreed that this is increasing (Spink *et al.*, 1944, 1945; Bondi and Dietz, 1945; Gallardo, 1945: Plough, 1945; Harley *et al.*, 1946; Barber and Rozwadowska-Dowzenko, 1948). Results of investigations of a series of infections occurring in a single hospital, however, are difficult to assess, as such institutions often seem to be breeding-grounds of a particular strain of pathogenic staphylococcus. Thus in previous studies in a single hospital by one of us (Barber, 1947a, 1947b; Barber and Rozwadowska-Dowzenko, 1948) it was found that 59 of 100 cases of staphylococcal infection investigated in 1948 yielded penicillin-resistant staphylococci, whereas the incidence in a similar series was 38% in 1947 and 14.1% in 1946. Each year, however, it was found that a significantly high proportion of the penicillin-resistant strains when typed by the bacteriophage method fell into the 6/47 group, suggesting that most of the penicillin-resistant infections might have been caused by a single strain of staphylococci.

Recent experience, however, has led us to the conclusion that a large number of penicillin-resistant staphylococci isolated from infections in widely separated hospitals belong to the 6/47 phage group. In the present investigation, therefore, staphylococci isolated from a series of 100 cases of infection occurring in this hospital have all been tested for penicillin sensitivity and phage-typed to see if the two could be correlated.

Methods

During the investigation all cultures of staphylococci (usually on blood-agar plates) obtained from cases of infection were collected from the routine laboratory. From each primary plate 10 colonies were picked off and streaked on to penicillin ditch-plates, the ditch containing 10 units of penicillin per ml. The remaining growth was then emulsified in broth and plated out on a similar penicillin ditch-plate in order to detect small numbers of penicillin-resistant organisms which might otherwise have been missed. After incubation overnight the plates were examined. If all colonies from a single specimen showed a similar reaction to penicillin one was picked off into "lemco" broth for further investigation. If penicillin-sensitive and penicillin-resistant staphylococci were present, one colony of each was similarly picked off.

All staphylococci were tested for coagulase by the slide method and only coagulase-positive strains included in the series. Later all strains in the series were tested for haemolysin production by the method of Gillespie and Simpson (1948), and strains giving doubtful or negative results were tested for coagulase production by the tube method of Fisk (1940) and for haemolysin by the method described by McFarlan (1938).

All penicillin-resistant strains were tested for penicillinase production by the method described by Barber (1947a); 17 of them were tested by the serial dilution method in broth, using two different-sized inocula in each case, as recommended by Gilson and Parker (1948). Sensitivity to streptomycin was also tested on ditch-plates, the ditch containing 100 units of streptomycin per ml., and to sulphonamides on ditch-plates made of laked horse-blood agar as recommended by Harper and Cawston (1945), the ditch containing 1 in 5,000 sulphathiazole. All ditch-plates, whether for testing penicillin, streptomycin, or sulphonamide sensitivity, were kept for 24 hours before use to allow diffusion of the chemotherapeutic agent, and part of every ditch-plate was seeded with the Oxford staphylococcus as a control. Phage-typing of all strains was carried out by the method now used at the Central Public Health Laboratory, using the same 25 filtrates. The method is based on the work of Wilson and Atkinson (1945).

Penicillin Sensitivity

Specimens were examined from 100 consecutive patients with infection due to coagulase-positive staphylococci (hereafter referred to as *Staph. pyogenes*). The results are given in Table I, in-patients and out-patients being separated. From 35 patients penicillin-resistant strains of *Staph. pyogenes* were isolated: from 24, all colonies tested were resistant to penicillin; from 11, sensitive and resistant colonies were isolated in each case from a single specimen. Thus 111 strains of *Staph. pyogenes* were obtained from 100 specimens. The difference between sensitive and resistant strains was clear-cut in every instance. All the penicillin-resistant colonies when streaked across the penicillin ditch-plates grew at least to the ditch, whereas the sensitive colonies showed an area of inhibition similar to that shown by the Oxford staphylococcus. It will be seen from Table I that the incidence of resistant strains was greater in in-patients than in out-patients. The results, analysed according to type of infection, are shown in Table II.

TABLE I.—*Analysis of Patients Yielding Staph. Pyogenes in Relation to Penicillin Sensitivity*

Inadequate information	1	—
	100	35

Previous treatment with penicillin was studied to see if this had any relation to the incidence of resistant strains. In only 67 of the patients was information regarding penicillin treatment available. Penicillin sensitivity in relation to treatment within the preceding three months in this group is shown in Table III.

TABLE III.—*Relation of Previous Treatment to Incidence of Resistant Strains*

	Penicillin Treatment within Previous 3 Months	No Penicillin Before Specimen Taken
Penicillin-sensitive strains only isolated	19	22
Penicillin-resistant strains isolated	22	8
Penicillin-sensitive and penicillin-resistant strains isolated	3	6

It will be seen that 22 of 41 patients who had been treated with penicillin yielded penicillin-resistant staphylococci, whereas only eight of 30 patients not treated with penicillin yielded such strains. One patient with an axillary abscess had a specimen taken before receiving any penicillin, and this yielded a very few colonies of penicillin-resistant and a heavy growth of penicillin-sensitive *Staph. pyogenes*. Treatment with penicillin was then started, and three weeks later a specimen of pus was received which yielded a heavy growth of *Staph. pyogenes*, and all colonies tested were penicillin-resistant.

The incidence of penicillin-resistant strains was correlated with length of hospital treatment in 46 cases, and the figures are given in Table IV. It will be seen that only 4 out of 22 patients who had been attending the hospital for a week or less yielded penicillin-resistant strains, whereas 10 of 18 patients who had been attending for a fortnight or more yielded such organisms.

TABLE IV.—*Incidence of Penicillin-resistant Strains of Staph. Pyogenes in Relation to Length of Treatment in this Hospital*

No. of Days under Treatment	Patients Yielding			Total

The figures in parentheses refer to the number of out-patients in each group.

Degree and Type of Resistance to Penicillin

All 35 penicillin-resistant strains destroyed penicillin. As is now well recognized (Luria, 1946; Barber, 1947a) the degree of resistance of such organisms when measured in the laboratory may vary many hundredfold according to the size of inoculum used. It is therefore extremely difficult to devise a test giving accurate information on the degree of resistance which will help the clinician in deciding the probable effect of penicillin in a particular case of infection. Gilson and Parker (1948) have suggested that the double sensitivity test in broth, using two different-sized inocula, is the most informative, as the results obtained are directly related to the degree and rate of penicillinase production. This test was carried out on 17 of the resistant strains of *Staph. pyogenes* isolated in this series (Table V). It will be seen that a large inoculum was

TABLE V.—*Showing Degree of Resistance*

Greatest Concentration of Penicillin Permitting Growth		No. of Strains

12·5 „	0·03 u./ml.	1
0·03 „	0·03 u./ml.	Oxford Staphylococcus

able to grow in from 12.5 to 50 units per ml., whereas a small inoculum was able to grow only in from 0.03 to 4 units per ml.

Phage-typing

All the 111 strains of *Staph. pyogenes* were phage-typed, and the results in relation to penicillin sensitivity are given in Table VI. Cultures reacting with one or more closely

TABLE VI.—*Phage Groups of 111 Strains of Staph. Pyogenes Isolated in Present Series*

related phages have been grouped together, and the strains in a particular group do not all give identical reactions. Of those classified as 6/7/47 nearly all reacted strongly with phage 47, and many also reacted with various combinations of 6, 7, and 3298. A few strains included in this group were sensitive to phage 6 or phage 7 only. Group 29/31/52, again, consists of strains showing varying reactions with one or more of these three phages. Nearly all the strains classified as 3 were sensitive to only one of the phages 3A, 3B, and 3C, and similarly strains in the 42 group reacted only with one of the phages 42B, 42C, 42D, and 42E. Apart from trace reactions, the 52A strains reacted with this phage alone. The non-typable group consists mainly of strains giving no reactions, but includes a few which were very sensitive and could not be classified.

It will be seen from Table VI that of the 35 penicillin-resistant strains as many as 24 fell into the 6/7/47 group, and that the only other typable strains belong to type 52A. The penicillin-sensitive strains, on the other hand, were distributed among all the groups, only nine out of 76 belonging to group 6/7/47.

As mentioned above, penicillin-sensitive and penicillin-resistant strains were isolated from the same patient in 11 cases. These 11 pairs of strains were phage-typed and the results are given in Table VII. In nine of the 11 pairs the

TABLE VII.—*Phage Types of Pairs of Strains Isolated from the Same Patient*

N.T. = Non-typable. * Side-reactions.

two appear to be different in phage-type, but it is unfortunate that in eight cases one of the pair is non-typable. From one of these 11 patients penicillin-resistant and penicillin-sensitive strains of *Staph. pyogenes* were isolated from both the lesion (sycosis barbae) and the nose. From each site the penicillin-resistant strain was phage type 6/47 and the penicillin-sensitive strain non-typable.

It occurred to us that the apparent correlation of penicillin resistance and phage group 6/7/47 might be a purely local phenomenon. A number of penicillinase-producing strains of *Staph. pyogenes* isolated from patients in widely separated hospitals were therefore collected together and phage-typed. The cultures from Hammersmith Hospital and the General Lying-In Hospital, S.E.1, were already in our possession, and the cultures from Canterbury, Manchester, and the West London Hospital were kindly sent by Dr. Forbes, Dr. Martyn, and Dr. Morris respectively. Except for the cultures from Manchester, which were isolated from healthy infants, all strains came from cases of infection. The results are given in Table VIII.

TABLE VIII.—*Phage Types of Penicillin-resistant Strains of Staph. Pyogenes Isolated from Patients*

Phage Group	Source						Total
	Hammersmith Hospital	St. Thomas's Hospital	General Lying-in Hospital, S.E.1	West London Hospital	Kent and Canterbury Hospital	St. Mary's Hospital, Manchester	
6/7/47	25	27	0	1	27	5	85
52A	1	4	15	0	1	0	21
42	3	0	0	0	0	0	3
3	1	0	0	0	0	0	1
29/31/52	1	0	0	0	0	0	1
N.T.	3	8	13	0	4	1	29
Total	34	39	28	1	32	6	140

In all, 140 strains were tested and as many as 85 (61%) fell into the 6/7/47 group. Apart from non-typable strains the only other large group is 52A. This is mainly due to an outbreak of infection among the babies at the General Lying-In Hospital which at the time of writing is under investigation. Nearly all the infections occurring at present in this maternity hospital are due to penicillinase-producing *Staph. pyogenes* and, as will be seen in the table, most of the strains are phage type 52A. A very large number of nurses in the hospital are carrying a similar organism in the nose.

Streptomycin and Sulphonamide Sensitivity

All 111 strains were tested for sensitivity to streptomycin and sulphonamides. The results are presented in relation to penicillin sensitivity in Table IX. All strains showed a

TABLE IX.—*Streptomycin and Sulphathiazole Sensitivity of 111 Strains of Staph. Pyogenes*

	Penicillin-sensitive	Penicillin-resistant	Total
Streptomycin-sensitive ..	76	35	111
Streptomycin-resistant ..	0	0	0
Sulphathiazole-sensitive ..	72	18	90
Sulphathiazole-resistant ..	4	17	21

sensitivity to streptomycin comparable to that of the Oxford staphylococcus. One of the patients, who had a lung abscess infected with penicillin-resistant *Staph. pyogenes, Proteus*, and non-haemolytic streptococci, was subsequently treated with streptomycin. Within five days the *Staph. pyogenes* had become highly resistant to this antibiotic.

Twenty-one of the 111 strains were considerably more resistant to sulphathiazole than the Oxford staphylococcus, and 19 of these strains grew at least to the edge of the ditch containing 1 in 5,000 sulphathiazole. It is interesting that 17 of the 21 sulphathiazole-resistant strains were also penicillin-resistant. Eight of the patients yielding sulphonamide-resistant strains had had some form of sulphonamide treatment before the specimen was taken, eight had not, and from five information in relation to treatment is not available.

α-Toxin Production

The strains isolated in the present series were all coagulase-positive on testing by the slide method. As Schwabacher, Cunliffe, Williams, and Harper (1945) and Christie, North, and Parkin (1946) have suggested that the production of α-lysin is more closely correlated with pathogenicity than coagulase production, all the strains were examined for α-toxin production, using the sheep-blood plate method of Gillespie and Simpson (1948). Of the 111 strains, 101 were α-toxigenic, two were negative, and eight were regarded as giving doubtful reactions. The negative and doubtful strains were tested for coagulase by the tube method of Fisk (1940) and found to be positive. The doubtful reactions on the sheep-blood agar plates were due in some instances to the simultaneous production of β-toxin in amounts sufficient to mask the appearances due to the α-toxin. On testing the eight doubtful strains for the production of α-toxin in broth, using the method of McFarlan (1938), four were found to be positive, while the remaining four were negative, as also were the two strains found to be negative by the sheep-blood plate method. Thus of the 111 coagulase-positive strains 105 were α-toxigenic.

Of the non-toxigenic strains, three belonged to phage type 3C; the remainder were non-typable.

Discussion

It is remarkable that such a high proportion of penicillin-resistant strains of *Staph. pyogenes*, isolated from patients in widely different hospitals, should belong to phage group 6/7/47. While in the present state of our knowledge it is possible only to speculate on the meaning of this, it may well be of considerable epidemiological importance. It is possible that strains of phage group 6/7/47 are genetically less stable than those of other phage groups, and have thus given rise to penicillin-resistant mutants more readily. A significant number of the remaining penicillin-resistant strains were type 52A, but nearly all these were isolated from neonatal infections occurring in a single maternity hospital over a period of three months. It is interesting that *Staph. pyogenes* of phage type 52A has been isolated from the noses of many nurses in this maternity hospital, and that some of the strains are sensitive to penicillin whereas others are resistant. It is possible that an originally sensitive strain of *Staph. pyogenes* carried in this hospital has recently given rise to a penicillin-resistant mutant which has now established itself there.

The ultimate origin of penicillin-destroying strains of *Staph. pyogenes* is still undecided. Spink and Ferris (1947) favour the hypothesis that such strains arise as mutants from penicillin-sensitive organisms. The work of Barber (1949) on the readiness with which, *in vitro*, penicillinase-producing staphylococci give rise to penicillin-sensitive variants supports this theory. Penicillin-destroying mutants, however, cannot be induced by growing penicillin-sensitive strains of *Staph. pyogenes* in penicillin *in vitro*. Spink *et al.* (1945, 1947) claim that such a change may be induced *in vivo* by penicillin treatment. As, however, their strains of *Staph. pyogenes* were not typed, it is possible that they were dealing with mixed infections due to penicillin-sensitive and penicillin-resistant strains of different types; that the latter, initially in the minority, were favoured at the expense of the former, and thus by a simple process of selection ultimately supplanted the penicillin-sensitive organisms.

Such mixtures of penicillin-sensitive and penicillin-resistant strains of *Staph. pyogenes* have now been isolated from the same patient on many occasions, and in most cases where such pairs have been phage-typed they have been found to give different reactions. Of 11 such pairs in the present series nine gave different phage reactions, and it seems likely that they were different phage types, although it is impossible to be quite certain of this where one of the pair was non-typable. In previous studies (Barber, 1947a, 1947b; Barber and Rozwadowska-Dowzenko, 1948) 10 such pairs were phage-typed and eight pairs were shown to be of different types.

Whatever the ultimate origin of penicillin-destroying strains of *Staph. pyogenes*, it seems likely (Barber and Rozwadowska-Dowzenko, 1948) that selection plays a large part in the increasing incidence of such strains in hospitals. The work of Harley *et al.* (1946) and Forbes (1949) further makes it clear that the incidence of penicillin-resistant strains isolated from staphylococcal infections in hospital in-patients is much greater than that in out-patients. In the present study it will be seen that 20 of 49 in-patients yielded penicillin-resistant strains compared with 15 of 51 out-patients, and that there was a significantly higher incidence of penicillin-resistant organisms in patients who had been under hospital treatment for more than a fortnight.

Kirby (1944) first pointed out that penicillin-resistant strains of *Staph. pyogenes* isolated from infective processes were characterized by the production of a powerful penicillin-inactivator. Since then Spink, Hall, and Ferris (1945), Bondi and Dietz (1945), Gots (1945), Barber (1947a, 1947b), Barber and Rozwadowska-Dowzenko (1948), Martin and Whitehead (1949), Martyn (1949), and Forbes (1949) have recorded studies in which all penicillin-resistant strains of *Staph. pyogenes* isolated from cases of infection or [illegible] carriers were shown to destroy penicillin. The [illegible] strains isolated in the present series likewise have this [illegible]ty.

Lurie (1946) and Barber (1947a) have both shown that the degree of resistance of penicillinase-producing organisms recorded in the laboratory was dependent on the size of inoculum used. In the present series it will be seen (Table V) that with many strains a small inoculum was

sensitive to less than 1 unit of penicillin per ml., whereas a large inoculum grew in from 12.5 to 50 units per ml. Thus the heaviness of the infection is the most important factor in deciding whether a patient infected with such an organism will benefit by penicillin treatment. As it is usually impossible to determine this, elaborate laboratory tests designed to show degree of sensitivity or rate of penicillinase production are valueless. It should further be emphasized that where a small inoculum is used in testing penicillin sensitivity the type of resistant organism here described may easily be missed.

The differentiation of pathogenic from non-pathogenic staphylococci in the laboratory has received considerable attention lately. Schwabacher, Cunliffe, Williams, and Harper (1945) and Christie, North, and Parkin (1946) found a small number of strains which were coagulase-positive but did not produce α-lysin, and both sets of workers considered the latter test to be more closely correlated with pathogenicity. In the present investigation all 111 strains were coagulase-positive and 105 were α-toxigenic. Although no evidence could be obtained to indicate that the α-lysin-negative strains were less pathogenic than the others, none of them came from very serious cases of infection.

Summary

Out of 100 cases of infection with *Staph. pyogenes* occurring in this hospital 35 yielded penicillin-resistant strains. In 24 cases all colonies tested were penicillin-resistant and in 11 both sensitive and resistant strains were isolated.

All penicillin-resistant strains were shown to destroy penicillin. Seventeen were tested for penicillin sensitivity, using two different-sized inocula, and it was found that whereas a small inoculum was sensitive to from 0.06 to 4 units per ml. a large inoculum grew in from 12.5 to 50 units per ml.

Twenty-four of the 35 penicillin-resistant strains were shown to belong to phage group 6/7/47, whereas only nine of 76 penicillin-sensitive strains fell into this group. When 140 penicillin-resistant strains isolated from patients in a variety of hospitals were phage-typed, 85 were found to belong to the 6/7/47 group.

All strains were initially sensitive to streptomycin. A strain from one patient became resistant after five days' treatment with this antibiotic.

Twenty-one of the 111 strains were resistant to sulphathiazole, and 17 of these were also resistant to penicillin.

All 111 strains were coagulase-positive; 105 were α-toxigenic.

We are grateful to Dr. R. E. O. Williams and the staff of the Staphylococcal Reference Laboratory for teaching us to phage-type staphylococci and for supplying us with a set of filtrates. We should also like to thank Dr. J. Bamforth and the staff of the Jenner Laboratory for supplying us with the specimens on which this work was based, Dr. Bhatia for assistance with some of the penicillin-sensitivity tests, and Dr. Forbes, Dr. Martyn, and Dr. Morris for sending us cultures of penicillin-resistant *Staph. pyogenes*.

INFECTION WITH PENICILLIN-RESISTANT STAPHYLOCOCCI IN HOSPITAL AND GENERAL PRACTICE

BY

G. B. FORBES, M.B., Ch.B.

Assistant Pathologist, Kent and Canterbury Hospital

The isolation of penicillin-resistant staphylococci from clinical sources, at one time a rare event, is now a commonplace. The great majority of these strains possess a natural resistance to penicillin by virtue of their ability to produce a penicillin-neutralizing enzyme, penicillinase (Kirby, 1944; Bondi and Deitz, 1945). Some indication of the frequency with which penicillinase-producing staphylococci are encountered in hospital practice, and the rising proportion of staphylococcal infections due to these strains, can be gauged from the work of Barber, who recorded a progressive increase in the incidence of infections with resistant strains from 14.1% in 1946 to 59% in 1948 (Barber, 1947a, 1947b; Barber and Rozwadowska-Dowzenko, 1948).

Dr. Barber's work has aroused much interest and not a little alarm, for at first sight it might appear that the power of penicillin in combating staphylococcal infection is decidedly on the wane. However, the results of an investigation carried out in a large hospital are not necessarily representative of the community as a whole, an opinion to which Dr. Barber herself subscribes when she states (Barber and Rozwadowska-Dowzenko, 1948): "Though penicillin-resistant strains of *Staph. pyogenes* are now appearing with increasing frequency in many hospitals, this is probably not the case in the community at large." This statement receives substantiation from the results of an investigation carried out at this hospital during the past 12 months.

Outline of Investigation

Staphylococci isolated on routine culture were in the first instance tested for coagulase-production by the method of Gillespie (1943) and sensitivity to penicillin on ditch-plates, using 10 units of penicillin per ml. of agar in the ditch. Coagulase-positive strains were then subcultured and set aside for further investigation, including a quantitative estimation of penicillin sensitivity (using serial dilutions of penicillin in 1-ml. amounts of broth and an inoculum of 0.02 ml. of a 1 in 100 dilution of a 24-hour broth culture), production of penicillinase, and sensitivity to streptomycin.

In the meantime further information regarding the source of the specimens which yielded coagulase-positive staphylococci was obtained by questioning patients and nursing staff, and in some cases examining the lesions from which the specimens were obtained. In particular it was noted whether the patient was an in-patient or out-patient not only at the time the specimen was collected but also at

the time that infection first became apparent, and whether the patient was having or had had penicillin treatment. Finally, attention was paid to the nature of the specimens submitted for examination, and to the amount and purity of growth on primary isolation, with a view to ensuring that the staphylococci were both pyogenic and truly pathogenic. As one would expect from the mode of selection, the great majority of strains accepted for analysis were from specimens of frank pus or purulent material from boils, abscesses, septic fingers, infected wounds, etc., and in nearly all cases the growth of staphylococci on primary culture was heavy and pure.

Analysis of 120 Strains of Staph. pyogenes

One hundred and twenty strains of *Staph. pyogenes* from the same number of patients were investigated. All but three were of the aureus variety; the three albus strains were strongly coagulase-positive on repeated examination, were present in pure culture on primary isolation, and the source of the strains left no doubt that they had been actively pathogenic. Of these 120 strains 73 (60.8%) were sensitive to penicillin and 47 (39.2%) resistant. The sensitive strains possessed a degree of sensitivity approximately equal to that shown by the control Oxford staphylococcus, and none produced penicillinase. On the other hand, all the resistant strains were penicillinase-producers. The resistance was gross in all cases both when tested on the ditch-plate (growth extending up to and over the ditch) and when estimated quantitatively, the minimal concentration of penicillin required to inhibit growth varying from 5 to 400 times that required to inhibit the control strain of Oxford staphylococcus (Table I).

TABLE I.—*Degree of Resistance of 41* Resistant Strains*

	Inhibiting Concentration of Penicillin in Units per ml.							
	32	16	8	4	2	1	0·8	0·4
No. of strains	1	3	5	9	7	2	6	8

* Six strains were not available for quantitative sensitivity tests. *Staph. aureus* (Oxford) was inhibited by 0·08 unit per ml.

Resistance to streptomycin was not encountered among any of these 120 strains, all possessing a sensitivity to this antibiotic of the same order as the control Oxford staphylococcus.

Analysis of 78 Out-patient and In-patient Strains

A separation of the 120 strains into those derived from out-patients and those from in-patients was then attempted. Inevitably a number of strains could not be placed in either of these categories. Thus a specimen may have been received from an in-patient, but the history of the case indicated that infection had occurred before the patient was admitted to hospital. Conversely, an out-patient may have given a history of a recent stay in hospital for the treatment of the condition from which he was suffering at the time the out-patient specimen was collected. Such cases in which the origin of the infecting strain was not clearly established have been omitted from this part of the analysis. Altogether 42 strains were unclassifiable, leaving a total of 78 strains which could be labelled with confidence "out-patient" or "in-patient" strains. The incidence of sensitive and resistant strains for this reduced series was 60.25% and 39.75% respectively, indicating that the exclusion of these 42 unclassifiable strains had not resulted in any significant deviation from the ratio for the original series, which was 60.8% sensitive to 39.2% resistant.

Out-patient Series.—The 40 strains which comprised the out-patient group were derived from specimens collected in the casualty and out-patient departments of this and neighbouring hospitals, and from specimens sent in by local practitioners. All but five of these strains were highly sensitive to penicillin, representing an incidence of sensitive strains of 87.5% and of resistant 12.5% (Table II).

TABLE II.—*Incidence of Penicillin-resistant Staph. pyogenes from 78 Patients with Staphylococcal Infection*

Source	No. of Strains	Resistant Strains
Out-patients	40	5 (12·5%)
In-patients	38	26 (68·4%)

In-patient Series.—Strains accepted for this series were recovered from patients whose infection had arisen during their stay in hospital. Thus infected operation wounds, infected plaster sores and bedsores, and neonatal infections were among the lesions which yielded in-patient strains. Of the 38 strains in this group no fewer than 26 (68.4%) were resistant, and 12 (31.6%) were sensitive. When these resistant strains were further analysed it was found that 11 of the 26 had originated in one department of the hospital, the maternity unit. This finding prompted a search for a carrier among the staff of the unit, and one of the senior nurses was found to be a persistent heavy nose-and-throat carrier of a penicillin-resistant coagulase-positive *Staph. aureus*. Phage-typing of eight patient strains, two carrier strains, and three strains isolated from the ward dust by exposing blood-agar plates was carried out through the courtesy of Dr. R. E. O. Williams at the Central Public Health Laboratory, Colindale. The results (Table III) show

TABLE III.—*Phage Reactions of Resistant Strains from Maternity Unit*

that all of the patients were infected with staphylococci belonging to one of two phage-types, that these same types were isolated from the ward dust, and that one of them (type 3A) was carried by a member of the nursing staff.

Effect of Previous Penicillin Therapy on the Resistance Rate

A history of treatment with penicillin for several days before the collection of the specimens was obtained from 41 patients. Twenty-five strains from these penicillin-treated patients were resistant and 16 were sensitive. Of 51 strains from patients not treated with penicillin 22 were resistant and 29 sensitive (Table IV). In short, the incidence

TABLE IV.—*Penicillin Therapy and Resistance Rate*

Source*	No. of Strains	Resistant Strains
Untreated patients	51	22 (42%)
Treated patients	41	25 (59%)

* The 92 patients which comprise this series include both out-patients and in-patients, and are independent of those quoted in Table II.

of resistant strains was slightly but not significantly higher in patients receiving penicillin.

In interpreting these findings it should be remembered that 42 of the 47 resistant strains were hospital strains, and, although they were isolated from 42 patients, it cannot be said that they were all distinct strains, for, as phage-typing has shown, dissemination of any one strain or the descendants of that strain by means of cross-infection had probably occurred to some extent. Consequently a number of the infecting strains were already resistant before the institution of penicillin treatment. All five out-patients and 20 in-patients from whom resistant strains were isolated were on large doses of penicillin when the specimens were collected. It is conceivable that the cells of the original infecting strain were for the most part susceptible, but that a number of variants within the strain enjoyed a measure of resistance. By the time the specimens were collected penicillin had eliminated the susceptible cocci, leaving a flora which was resistant.

Discussion

There is no doubt that staphylococcal infections due to penicillin-resistant strains are being encountered with increasing frequency in hospital practice. The reason for this unwelcome trend would seem to lie in the fact that the staphylococcal population of most hospitals at the present time is dominated by strains which possess a natural resistance, the inevitable consequence of the widespread use of penicillin during the past few years. By a process of natural selection these resistant strains have survived and propagated at the expense of susceptible breeds; and their presence in ward dust and the upper respiratory passages of members of the hospital staff, together with case-to-case infection, no doubt accounts for the high incidence of this type of infection in hospitals. By contrast, the environmental conditions which prevail in the community at large offer small scope for the perpetuation and dissemination of resistant strains, and one would anticipate a much lower incidence of infection due to these strains among the general population.

The carrier rate of penicillin-resistant staphylococci among hospital and non-hospital employees is under investigation and will be the subject of a later communication. Preliminary findings indicate that the rate of carriage of these strains by members of the staff of this hospital is disturbingly high. Of 50 ward nurses no fewer than 23 (46%) were found to carry in their anterior nares coagulase-positive *Staph. aureus* resistant to at least 1 unit of penicillin. The resistant strains all produced penicillinase. Of a control group of 50 office workers (not attached to the hospital) only one (2%) was found to be a nasal carrier of a penicillin-resistant strain.

From these and other observations one might attempt a grouping of staphylococcal infections according to the sensitivity to penicillin of the infecting strains, as follows. (*a*) Infection due to a pure sensitive strain the cells of which are all susceptible to the action of penicillin in adequate dosage. The majority of infections, especially those met with in general practice, fall into this group. (*b*) Infection due to a pure resistant strain—for example, hospital infection—which is naturally resistant to penicillin. (*c*) Infection due to a single strain, for the most part sensitive but containing a variable number of naturally resistant penicillinase-producing variants. Under the influence of penicillin such a strain may develop into a pure resistant strain owing to the elimination of penicillin-susceptible cells (Anderson *et al.*, 1944; Spink and Ferris, 1947). (*d*) Infection due to a sensitive staphylococcus complicated by superinfection with an insensitive strain of different phage type (Barber, 1947a, 1947b).

Recent reports on the high incidence of resistant strains have cast doubt on the competence of penicillin to deal with staphylococcal infections (leading article, *British Medical Journal*, 1947, 2, 874). The results of this study are presented in the hope of restoring confidence in penicillin for the treatment of staphylococcal infections in general practice. So far as the results of a limited study confined to one provincial hospital area are applicable to the general situation, it would seem that intelligent therapy with penicillin (and other measures when indicated) should effect a cure in nine of ten out-patients with staphylococcal sepsis. At the same time the results confirm the high proportion of hospital infections due to resistant strains: only one in every three patients with infection contracted during their stay in this hospital was eligible for penicillin therapy.

Penicillinase-producing strains of staphylococci are fully pathogenic (North and Christie, 1946; Barber, 1947a) and on occasion are capable of causing severe and sometimes fatal infections, such as staphylococcal septicaemia. Since resistance to penicillin appears to be specific, and not necessarily accompanied by resistance to either sulphonamides (Spink, Hall, and Ferris, 1945) or streptomycin, recourse may be had to one or both of the latter anti-staphylococcal agents in the treatment of severe infections due to penicillin-resistant staphylococci.

Summary

Seventy-eight strains of *Staph. pyogenes* from clinical sources have been analysed according to their sensitivity to penicillin. The resistance rate of strains derived from out-patients was 12.5% and from in-patients 68.4%.

All resistant strains produced penicillinase.

Many of the strains were already resistant before penicillin treatment was started.

The epidemiological and clinical significance of these findings has been briefly discussed. The frequency with which penicillin-resistant strains are carried in the anterior nares of ward nurses is thought to be partly responsible for the high proportion of hospital infections with resistant staphylococci.

My thanks are due to Dr. I. B. Morris for help and encouragement, and to the laboratory staff for technical assistance.

The June report of the British Control Commission for Germany says that the Rockefeller Institute has arranged a study tour in Denmark, England, and the U.S.A. for a number of young German medical officers of health, two of whom will probably come from the British Zone. The tour will last two to three months. In the hope that the proposed central narcotic administration for Western Germany may be modelled on British organization, arrangements are being made to send prospective officials to Britain for a 10-day visit to study British methods. No special shortages of medical supplies were reported during the month. Improvement in the supply of penicillin should enable a reserve to be built up again, and it is now sold more cheaply.

HOMOLOGOUS SERUM JAUNDICE

BY

DERMOT LEHANE, M.B., B.Ch.
Regional Blood Transfusion Officer

*CATHERINE M. S. KWANTES
*MARY GALTON UPWARD

AND

*DOROTHY ROSEMARY THOMSON
(From the Regional Blood Transfusion Centre, Liverpool)

In 1938 MacNalty drew attention to the fact that jaundice had followed the subcutaneous injection of convalescent measles serum; of 109 recipients 41 developed jaundice. Despite this and similar reports, little interest was aroused until in 1942 Sawyer *et al.* reported 28,585 cases among United States troops following inoculation against yellow fever with vaccine suspended in human serum. Subsequently there were reports of jaundice following the transfusion of human plasma or serum. In 1943 a memorandum was published (*Lancet*, 1943) by Medical Officers of the Ministry of Health reviewing the literature on homologous serum jaundice and reporting that recipients of plasma transfusions had developed jaundice. Spurling, Shone, and Vaughan (1946), in their survey of 1,054 patients given plasma, found that 7.3% developed jaundice, whereas in 891 patients given whole blood there were no cases of jaundice which could be attributed definitely to transfusion. Brightman and Korns (1947) investigated 649 cases in which plasma had been transfused, and found a 4.5% incidence of jaundice.

From these and other reports it was obvious that certain pools of plasma were definitely icterogenic while others were non-icterogenic. It therefore seemed probable that the icterogenic factor was present in the blood of a small percentage of donors, and that the inclusion of such donors' blood in the pools was responsible for their icterogenicity. It was considered likely that by limiting the number of donors contributing to each pool it should be possible to limit the dissemination of the icterogenic agent, and accordingly small-pool plasma was introduced in June, 1949.

This paper reports the results of a survey carried out during the period October, 1945, to March, 1948, in the region served by the Liverpool Regional Blood Transfusion Centre. The main object of the survey was to obtain comparative figures for the incidence of homologous serum jaundice following the transfusion of different blood products. The transfusion materials investigated were:

Large-Pool Plasma.—This consisted of plasma processed at the Medical Research Council Drying Plant at Cambridge or the Army Blood Supply Depot at Bristol before June, 1945, each pool being derived from not fewer than 300 donors; this plasma was Seitz-filtered before drying. In addition to this a small quantity of similar large-pool dried serum, supplied during the war by the Government of the Dominion of Canada and the Canadian Red Cross Society, was used. It was considered that no useful purpose would be served by recording separately cases receiving large-pool plasma and large-pool serum.

Small-Pool Plasma.—Consisting of unfiltered plasma, collected and processed since June, 1945, each pool being derived from not more than 10 donors.

Whole Blood.—Collected and bottled by the standard technique of the National Blood Transfusion Service.

*Working with a grant from the Medical Research Council.

Method of Follow-up

The survey was carried out on the following lines: (1) Names of patients receiving transfusions were reported to the Regional Transfusion Centre by the hospitals. (2) Permission was obtained from the hospitals to abstract from their records information such as the patient's home address, the condition for which the transfusion was given, and other relevant details. (3) After a period of six months from the date of transfusion had elapsed a letter was sent to the patient's home address. This letter was in the form of a general inquiry regarding the health of the patient following his discharge from hospital. A questionary was included with the letter, and the patient was asked to indicate whether he had had various illnesses, including jaundice. On receipt of the completed questionary, those patients whose replies indicated that jaundice had occurred were visited.

This "home visit" was essential for the discovery of cases of homologous serum jaundice, because very few were reported by hospitals or private practitioners. Furthermore, it was necessary to ascertain whether jaundice had occurred in other members of the patient's household, as if this had occurred it was doubtful whether the illness of the recipient could be attributed to transfusion. When full details of the course of the illness had been obtained from the patient, further inquiries were made from the physician who had treated the case, so establishing a comprehensive history and accurate diagnosis.

The "home visit" was omitted in the case of death of the recipient, and a careful check of the case papers and the private practitioner's records was carried out to ensure that homologous serum jaundice had not occurred.

A diagnosis of homologous serum jaundice was made only if each of the following conditions was fulfilled: (1) jaundice occurring one to six months after transfusion; (2) absence of history of contact with cases of infective hepatitis; and (3) absence of other pathological causes of jaundice.

TABLE I.—*Particulars of Patients given Blood, Large-Pool Dried Plasma, and/or Small-Pool Dried Plasma*

	Blood Alone	Large-Pool Plasma	Blood and Large-Pool Plasma	Blood and Small-Pool Plasma	Small-Pool Plasma	Totals
Total No. of patients followed up	4,270	893	666	703	584	7,116
No. of patients untraced	704 (16·4%)	133 (14·8%)	173 (25·9%)	83 (11·8%)	50 (8·5%)	1,143 (16·1%)
No. of patients traced	3,566	760	493	620	534	5,973
No. of deaths within 6 months of transfusion (not with jaundice)	770 (21·6%)	307 (40·4%)	126 (25·5%)	202 (32·6%)	138 (25·8%)	1,543 (25·8%)
No. of surviving patients upon whom incidence of jaundice is based	2,796	453	367	418	396	4,430
No. who reported no history of jaundice within 6 months	2,772 (99·1%)	399 (88·1%)	320 (87·2%)	410 (98·1%)	391 (98·8%)	4,292 (96·9%)
No. with unconfirmed history of jaundice or doubtful aetiology	2 (0·1%)	0 —	1 (0·3%)	1 (0·2%)	0 —	4 (0·1%)
No. who developed jaundice attributed to transfusion within 6 months after transfusion	22 (0·8%)	54 (11·9%)	46 (12·5%)	7 (1·7%)	5 (1·3%)	134 (3·0%)
No. who died of jaundice	0 —	3 (0·7%)	3 (0·8%)	1 (0·2%)	0 —	7 (0·2%)

Overall case mortality rate = 5·22%.

In three of the four cases listed as "doubtful" the history of jaundice was extremely [illegible] confirmation of the illness from the patient [illegible] had been in contact with a case of infective hepatitis.

Of the 1,543 patients who died within six months of transfusion without evidence of jaundice or hepatitis, 1,308 (84.8%) died within one month and 235 (15.2%) within the next five months.

Results of Follow-up

Particulars of the patients followed up are shown in Table I. Letters were sent to 7,116 recipients of transfusion, and 5,973 were traced, of whom 1,543 were reported to have died within six months, leaving 4,430 to be interviewed.

Classifying these according to fluid transfused, 2,796 received whole blood, 453 large-pool plasma, 396 small-pool plasma, 367 blood and large-pool plasma, and 418 blood and small-pool plasma. In all, 134 cases of jaundice were discovered.

The 2,796 recipients of whole blood were given 6,210 bottles, equal to an average of 2.2 bottles per patient. Twenty-two cases of homologous serum jaundice occurred following the use of these 6,210 bottles of blood: if each case of jaundice received only one bottle of icterogenic blood, and assuming that each donor gave only one bottle of blood, then at least 0.35% of the donors were carrying an icterogenic agent in their blood stream with no symptoms indicative of disease. It is unlikely that all recipients were susceptible, so that the rate is possibly higher than this.

Among those who received large-pool plasma and blood and large-pool plasma 100 cases of homologous serum jaundice occurred. The batches of plasma used in six of these cases were also found to be icterogenic when used in other areas. Seventy-one of the cases followed the use of 25 batches—for example, Batch No. C307 was involved in seven cases. Each of the remaining 23 cases was associated with a different batch of plasma.

Similarly, among those receiving small-pool plasma and blood and small-pool plasma the plasma used in six of the 12 cases was drawn from 13 different batches. The remaining six cases each followed the use of a different batch. These batches were not associated with jaundice in any other recipients.

It is impossible to give an attack rate for any particular batch of icterogenic plasma in this series, but it was found, for example, that Batch No. C307 was given to 15 patients without complication, although this batch was followed by jaundice in seven other patients. The total number of recipients of this batch, which was widely distributed in other areas, is not known.

Fatal Cases.—There were seven deaths from homologous serum jaundice in the series—namely, three in the large-pool plasma group, three in the blood and large-pool plasma group, and one in the blood and small-pool plasma group. There were no fatal cases in the groups which received small-pool plasma or whole blood (see Table II).

TABLE II.—*Fatal Cases*

Illness	Age	Sex	Incubation Period	Transfusion Fluid
Incomplete abortion ..	36	F	12 weeks	Blood and small-pool plasma
Post-partum haemorrhage	28	F	16 ,,	Blood and large-pool plasma
Arthrodesis of hip ..	55	M	6 ,,	,, ,, ,, ,,
Ruptured spleen	40	M	6 ,,	,, ,, ,, ,,
Multiple injuries and shock	73	M	9 ,,	Large-pool plasma
Prostatectomy	67	M	13 ,,	,, ,,
Partial gastrectomy ..	65	M	6 ,,	,, ,,

Incubation Period.—The incubation period of the illness varied considerably in the cases investigated, but unless the jaundice occurred between one and six months after transfusion it was not classified as homologous serum jaundice. In fact, no cases of jaundice occurred within one month of the transfusion. In the majority of cases the jaundice occurred 8 to 16 weeks after transfusion (see Chart).

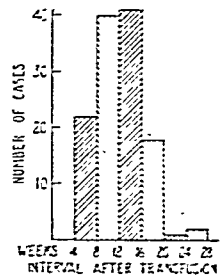

Chart showing incubation period. Ten cases are omitted because the incubation period could not be accurately determined.

Nature of the Illness.—Eight of the cases (6%) were very mild, with an illness lasting less than one week, and three of these were indisposed for two to three days only. On the other hand, two cases terminated fatally within three days of the onset of symptoms. Twenty-one cases (15.7%) were severe, with an illness which lasted six weeks or more, while the remaining 98 cases (73.7%) were ill for one month or less and their symptoms were not severe. The average duration of illness was 30.5 days, with extremes of two and 112 days. The incidence of the various symptoms and signs is shown in Table III.

TABLE III.—*Symptoms and Signs*

Symptoms and Signs	No. of Cases
Jaundice	134 (100%)
Nausea, vomiting, and anorexia	60 (44·8%)
Lassitude	35 (26·1%)
Joint pains	33 (24·6%)
Skin rash	21 (15·7%)
Epigastric pain	14 (10·4%)

Age Incidence.—The age incidence is set out in Table IV; the upper and lower limits were 73 years and 9 years respectively.

TABLE IV.—*Age Incidence*

Age Group	No. of Patients Transfused		No. of Cases of Jaundice	
	Blood Alone	Plasma and Plasma and Blood	Blood Alone	Plasma and Plasma and Blood
0–10 ..	87	127	—	1 (0·8%)
11–20 ..	136	104	2 (1·4%)	6 (5·7%)
21–30 ..	655	294	6 (0·9%)	20 (6·8%)
31–40 ..	758	339	7 (0·9%)	24 (7·1%)
41–50 ..	450	254	2 (0·4%)	23 (9·1%)
51–60 ..	294	204	2 (0·6%)	19 (9·3%)
61–70 ..	267	211	2 (0·7%)	17 (8·1%)
71–80 ..	112	88	1 (0·8%)	2 (2·2%)
81–90 ..	7	13	—	—
Totals ..	2,796	1,634	22 (0·8%)	112 (6·1%)

The illness which necessitated transfusion therapy was taken into account in all cases, but nothing significant was noted. Similarly, the cases were more or less equally distributed between the sexes, 71 (53%) being female and 63 (47%) male.

Discussion

In the present investigation the incidence of homologous serum jaundice (11.9%) found among the recipients of large-pool plasma is considerably higher than that reported by other workers. Of the 54 cases, three were fatal, whereas Spurling and others reported 77 cases, none of which was fatal.

In those patients who received small-pool plasma, on the other hand, the incidence of homologous serum jaundice was significantly lower, amounting to only 1.3%. The considerable reduction in the incidence of this complication of plasma transfusion seems to justify the decision made in 1945 to produce only small-pool plasma.

Of the recipients of whole blood 22 developed jaundice—i.e., 0.8% of the cases—whereas among 891 recipients investigated by Spurling and others six cases of jaundice (0.7%) were reported, but these were listed as "doubtful if due to transfusion."

Inquiry failed to reveal any increase in the incidence of infective hepatitis during the period under review in the North-West Region, the population of which is 3,250,000. In another part of England the attack rate per 1,000 per annum was 0.06 in 1945, 0.07 in 1946, and 0.04 in 1947 in a population of 2,600,000 (McFarlan—personal communication).

In the production of small-pool plasma a record of the donors who contributed to each pool was available, and a follow-up of these donors was carried out so far as was possible, but in only one out of the 63 donors traced was there a history of jaundice. In this case jaundice occurred three months after blood donation. No information such as history of contact with infective hepatitis or of inoculation was given. The donors whose bloods were involved in homologous serum jaundice in the whole-blood series were also followed up, but with negative results.

Summary

In the follow-up of 4,430 patients who had received transfusion therapy 134 (3%) cases of jaundice were discovered, of which seven (0.2%) terminated fatally.

Large-pool plasma and combined large-pool plasma and blood transfusions were responsible for 100 (74.6%) of the cases, six of which were fatal.

The incidence rates of homologous serum jaundice for small-pool plasma (1.3%) and for whole blood (0.8%) are not significantly different (difference/S.E. of difference = 1, approx.), but these rates differ very considerably from that of large-pool plasma (11.9%).

The findings suggest that at least 0.35% of donors are probably carriers of the icterogenic virus.

One of the German casualties of the war was the *Archiv für Schiffs- und Tropenhygiene*, and for over four years the Germans have been without a national journal devoted to tropical medicine. This gap has now been filled by the publication of the *Zeitschrift für Tropenmedizin und Parasitologie*, which is edited by workers at the Bernhard Nocht-Institut für Schiffs- und Tropenkrankheiten, Hamburg, and published by Georg Thieme, of Stuttgart. In their prefatory note the editors point out that, while opportunities for German workers in the Tropics are now almost non-existent, many problems concerning tropical medicine can be investigated in the laboratory at home, and that as a result of the war many cases of tropical disease in Germany make ample material available for clinical investigation. Subscription to the new journal is approximately £4 per annum. Dutch investigators also suffered a setback when publication of the *Geneeskundig Tijdschrift voor Nederlandsch Indië* was stopped by the Japanese in March, 1942, after having appeared without interruption since 1852. This journal was replaced in 1946 by the *Medisch Maandblad*. Both these journals have the disadvantage, so far as English readers are concerned, of being almost entirely in Dutch. To overcome this difficulty the Dutch have now commenced publication of an English-language quarterly journal of tropical medicine and hygiene, *Documenta Neerlandica et Indonesica de Morbis Tropicis*, with an editorial board representative both of the Netherlands and its overseas territories. Subscription to this journal is £1 2s. 6d. per annum, and it is published at Rivierenlaan 268, Amsterdam Z.

ISO-IMMUNIZATION BY BLOOD-GROUP FACTORS A AND B IN MAN

BY

PIERRE O. HUBINONT, M.D.

(From the Laboratoires d'Hygiène et de Bactériologie de la Faculté de Médecine, Université Libre de Bruxelles)

Much has been written about the possibility of the blood-group factors A and B acting in the same way as the Rh factor in the pathogenesis of haemolytic disease of the newborn. Jonsson (1936) gave the first immunological evidence, of a statistical nature, that heterospecific blood-group pregnancy (where the O or B mother bears a foetus of group A or AB) was accompanied by a rise of the anti-A haemolysin. Smith (1945) demonstrated that the anti-A or anti-B agglutinin titre rose only in the cases in which the heterospecific foetus was a secretor. The heterospecific pregnancy is then capable of inducing an immune response, but there are very few heterospecific foetuses that demonstrate haemolytic disease. In consequence, there must be some protective mechanism, several of which were reviewed by Tovey (1945).

There are, however, certain facts which focus the attention on the antibody itself. In 1946 we found in the blood of pregnant women who had previously been delivered of stillborn babies anti-A agglutinins reacting far more strongly at 37° than at 4° C. (Millet and Hubinont, 1946a ; Hubinont and Millet, 1946). Bruynoghe (1947) found an anti-B agglutinin of the same type in a case of haemolytic disease of the newborn. Since then we have met with several similar cases in which the clinical course was somewhat different from the classical haemolytic disease of the newborn. In all cases the foetus died *in utero* a few days before delivery or during labour.

Many authors—the first of them being Levine, Katzin, and Burnham (1940)—have emphasized that anti-Rh agglutinins react more strongly at 37° than at 4° C. Inversely, it is very well known that natural anti-A or anti-B agglutinins possess a thermal optimum at 4° C.

We verified that several normal agglutinins of rabbit serum (Millet and Hubinont, 1946b ; Hubinont, 1948a) and guinea-pig serum (Hubinont, 1947) showed, through immunization, the same change of thermal optimum that we found in our patients. Further investigations on the rabbit showed that hyperimmunization with sheep erythrocytes was often followed by the production of a blocking antibody, giving a prozone phenomenon in quantitative agglutination tests (Hubinont, 1948b).

We recently had the opportunity of studying the immune-response of a group B individual who was transfused by mistake with A_1 blood and eventually recovered: 75 ml. of whole blood had been injected before alarming symptoms appeared.

The serum was tested at regular intervals with A_1 and A_2 cells collected from the same donors. The tests were performed by the usual technique in tubes, using 0.9% saline as diluent, each test being performed simultaneously at 4° and 37° C. The results are shown in the Table.

On the day of transfusion both A_1 and A_2 cells were agglutinated with the same titre and thermal optimum. On the fourth day there was a small increase in titre, noticeably higher for A_1 than for A_2 cells. On the eighth day the thermal optimum for A_1 agglutination turned to 37° C. Finally, on the 30th day the agglutination was stronger at

37° C. for both A_1 and A_2 cells. Further, there was a prozone phenomenon in the test for A_1 agglutination at 4° C. It was shown by a blocking test (Race, 1944 ; Wiener, 1944) that this prozone was due to the presence of an anti-A blocking antibody.

Time of Test	Cells	Temp.	Serum Dilutions 1/1	1/2¹	1/2²	1/2³	1/2⁴	1/2⁵	1/2⁶	1/2⁷	1/2⁸	1/2⁹	T
Day of transfusion	A_1	37° C.	½	++	+	w	—	—	—	—	—	—	—

Scores for agglutination are given in arabic signs (for visual agglutination) and the signs usually employed for microscopical agglutination in Rh work (M.R.C. Memorandum, 1943).

Unfortunately the patient could not be followed up, and we are not aware of his actual agglutination pattern for A_1 and A_2 cells. Nevertheless, his immune response to an incompatible transfusion confirms our observation of ABO iso-immunization in pregnant women and of experimental hetero-immunization in rabbits.

Upon immunization with an antigen corresponding to a natural agglutinin present in the animal's serum (anti-A or anti-B in man, anti-sheep in rabbits), the first noticeable change would be a slight rise in titre, followed quickly by an inversion of the thermal optimum in quantitative agglutination tests. A further step would be the apparition of a prozone corresponding to the production of "blocking antibodies."

The *in-vitro* differences in the behaviour of "natural" cold anti-A and anti-B agglutinins and the "immune" warm anti-A and anti-B antibodies are probably dependent on their chemical structure, which would account for their harmfulness to the foetus. It is a significant fact that we found these warm agglutinins in the only instances quoted above with their particular clinical course, and that they were not found in uneventful heterospecific blood-group pregnancies.

Summary

A case of immune response to an incompatible blood-group transfusion is described. There is a definite difference *in vitro* between natural and immune anti-A agglutinins.

The same difference is found in maternal iso-immunization, the particular form of haemolytic disease following A and B sensitization being the death of the foetus *in utero*, either during the last days of pregnancy or at the time of delivery.

DIAGNOSIS AND TREATMENT OF CUTANEOUS ANTHRAX

BY

JOHN A. HOLGATE, M.B., Ch.B.

Demonstrator, Department of Physiology, University of Leeds; Formerly House-physician to the Department of Dermatology, General Infirmary at Leeds

AND

REGINALD A. HOLMAN, M.B., Ch.B.

Demonstrator, Department of Bacteriology, University of Leeds

Anthrax—a rare disease in this country—has many interesting and unusual facets. Probably first recorded by Virgil, it became prominent initially in Britain about the middle of the last century coincidentally with the importation of alpaca and mohair to Bradford. It was first notifiable so far as factories and workshops were concerned in 1896, and activity was rapidly directed towards its prevention in view of the high proportion of fatalities among affected workers—then some 20 to 30%. Local precautions in the form of protective clothing, the posting of information regarding the disease, washing facilities, and exhaust ventilation for certain processes were advocated by the Anthrax Investigation Board set up in Bradford by the Chamber of Commerce. Despite these the incidence remained high, though the dread and fatal form of pulmonary infection showed a rapid decline between 1881, when Mr. John Spear made his investigations, and 1905, when Dr. T. M. Legge gave the classical Milroy Lectures on industrial anthrax.

A further Anthrax Investigation Committee set up in 1913 advocated, in 1918, a process for wool and hair disinfection. Following up the committee's suggestions, Parliament passed the Anthrax Prevention Act in 1919, and by 1921 an experimental disinfecting station had been set up in Love Lane, Liverpool, to carry out the "Duckering process"—named after the secretary of the above committee—for wool and hair disinfection, and in succeeding years this process has proved its efficacy. Mention should be made of the excellent bacteriological investigations carried out for both the board and the committee by the late Dr. F. W. Eurich, professor of forensic medicine at the University of Leeds.

From 1890 to 1920 an increase in the incidence of anthrax was also noticed in the cattle of Great Britain, though the numbers were never comparable to those encountered in Russia, Siberia, China, and parts of India. Knowledge about the means of spread of the disease and the life history of the organism enabled measures to be taken which may be briefly summarized under the headings of—notification, isolation, and destruction of the sick animal or carcass, disinfection of the surroundings, and inoculation of other animals. These not only rapidly controlled the disease among cattle but also diminished the incidence among butchers, veterinarians, shepherds, and others associating with animals, the true index of which was never known, since only cases occurring in certain trades were then notifiable. This anomaly of notification was widely commented upon in coroners' courts, medical journals, and Parliament at the time.

In the four or five years following 1915 the incidence of anthrax increased both here and in America, the source being shaving-brushes made from infected hair. This source was soon recognized as being especially dangerous, since it was not confined to any particular trade or industry, claiming among its victims a professor of law and a

Congregational minister, to name but two, and precautions were rapidly taken—in particular an Order made under the Act of 1919 banning the importation into Britain of shaving-brushes of Japanese origin. Sporadic cases from this source have been reported up to 1939—some from brushes bought years previously, in which the spores had lain dormant until the unlucky coincidence of shaving-cut and spore ignited the powder of disease.

The disease contracted from wool and hair and that in animals are thus largely controllable, but there still remains a further common source of infection—namely, imported hides and skins. This source gives rise to cases not only in tanneries but also in dock workers, carters, and warehousemen, as well as very occasionally in persons coming in contact with leather. Methods aimed at killing the hardy spore in the hides tend to damage the material, and though suitable disinfecting processes have been claimed by Seymour-Jones, of Wrexham (and advocated by Ponder), and by others in Germany, they have not been adopted. Cases from this source arise from time to time, and the following is a report of eight such cases occurring in two tanneries in Leeds and district in a period of fourteen months.

Occupation and Source of Infection

All eight cases were of the cutaneous type of infection, and all occurred in men doing essentially the same tasks at two different tanneries (named for convenience "A" and "B") in widely separated areas. Tannery "A" deals mainly with goat-skins coming from various sources as indicated in Table I, but principally from East and West Africa. All six men from this tannery were employed opening the bales of skins, carrying the skins up to a sorting-shed, sorting them, and then sending them down a chute to the lime-yard when required. As one man after another fell victim other men took their place, and eventually they too became patients. Of the seven different men undertaking these tasks during the past fourteen months six have contracted anthrax. The previously reported cases occurring at this tannery were two in 1936 and two in 1946. Certain alterations have now been carried out in the hope of reducing the risk.

Tannery "B" deals with the hides chiefly from East and West Africa, though occasionally from South America and India. All are dry hides, as opposed to the wet salted variety which rarely give rise to infection. The duties of the men at this tannery are precisely the same as those at "A"—but owing to the demand for goods and the short-age of raw material there is very little storage of hides at present, and they are almost immediately taken into the water- and lime-vats on unbaling, and there is rushing in this system. During the eight-months period in which the cases occurred there were some 12 to 15 men working in this part of the tannery. There had been no previous cases.

At both tanneries the full regulations as laid down in various Acts are carried out, the men wearing protective clothing, and washing facilities and changing-rooms being provided. In the opinion of the authorities at these tanneries it is the increased demand for raw materials which has given rise to the present outbreak, the materials being collected from various remote regions in Africa where there is little or no control over the source of the hide or skin. No cases have ever occurred at either tannery in the processes carried out beyond the lime-vats.

Occurrence of Infection. Contact Cases

The necessity for a local skin abrasion together with the presence of the organism before the appearance of a malignant pustule has long been known, and is borne out by these cases, in all of which there was good cause for a local abrasion such as collar-chafing or shaving-cuts. Even in Case 4, in which the lesion was on the leg, there were also numerous flea-bites. It is interesting to speculate in this connexion whether a break in the lung "lining surface" is not also necessary before the development of pulmonary anthrax. Spore-laden dust was plentiful at tannery "A" and yet no pulmonary cases have occurred to date. Also the rapid decline in incidence of pulmonary anthrax from 1880 onwards parallels the improvement in general public health and the decline of tuberculosis in particular.

All cases presented the classical malignant pustule, and in all the diagnosis had been made by the patient or a fellow workman—from their knowledge of the disease obtained by experience or from a poster hung in the factory—and never by a physician. In some cases delay in admission was actually caused by the physician.

Man-to-man infection is surprisingly rare. There are recorded cases in the literature—Hodgson (1937) records two—but their number is small, and this is surprising in view of two points which can be seen in Tables I and III—namely, the length of time during which the patient may be in contact with his family, often in a small house, and the fact that his normal healthy skin may give a positive growth of organisms, showing the widespread nature of their distribution. The intact skin must in many cases be a barrier of unusual strength in preventing the appearance of contact infection.

TABLE I.—*Summary of Cases*

Diagnosis

This is made on the following three salient points.

1. *Appearance of Lesion.*—In all eight cases this was typical—a black, necrotic centre, a ring, partial or complete, of pearly translucent vesicles, the whole sitting on a red base on a hillock of widespread oedema. Certain other features aid the physician. The absence of pain with such a degree of oedema is noticeable. Practically the only local symptom encountered in this series was slight itching.

Earlier stages than this in the development of the lesions are described, the commonest being the large vesicle under which the black eschar forms, but these were not seen by us even in the patient who presented within 26 hours of the onset of disease. Constitutional symptoms and signs were not common. Only Case 4 presented with pyrexia, though Cases 3, 6, and 8 had pyrexia on the second or third day of treatment, with associated headache, malaise, and often pains in the bones. In Case 6 this may have been of other causation (see below).

2. *Occupation of Patient.*—At present this is a reasonably straightforward clue, anthrax occurring in those industries where exposure to infection is well known. A survey of the literature has shown that the disease may appear under most unlikely circumstances. For example, it may occur in carpet-layers, paper-hangers (from wall plaster), menders of sacks (which have carried bones, horns, or hooves), and carriers of potatoes (from soil), and from mink farms, elephant tusks, elephants at the London Zoo, etc. A physician may be forgiven for not suspecting the condition in patients in occupations such as these, but in persons connected with animals or animal products (especially imported ones) presenting with a localized skin lesion, or occasionally multiple lesions, anthrax should be a first consideration.

3. *Bacteriological Diagnosis and Investigations.*—These are the final proof, and were obtained in all our cases except Case 5, in which the first two criteria were adequately fulfilled—justifying treatment for anthrax. The following investigations were carried out in this series.

Bacteriological Examination

As soon as a case was suspected of being due to *Bacillus anthracis*, material from the local lesion was taken for investigation. The most practicable way of taking this material was found to be with a Pasteur pipette, plunging the point into the centre of a vesicle, or vesicles if confluent, and withdrawing the fluid. If there were no obvious vesicles, or they had burst, then material was aspirated from beneath the edge of the eschar. The fluid obtained was clear, yellow, or sanious in nature, there being no evidence of pus macroscopically.

As a routine this material was cultured aerobically on heated and fresh blood agar, and two thick films were made, stained with Gram and Leishman respectively. On examination of the Gram film a long time was often spent before coming across one, two, or perhaps a small chain of bacilli—this being especially true in five of the seven positive cases. In the other two the vesicular fluid was heavily infected with the organism. In no case was there any marked polymorphonuclear leucocytic response. In the seven positive cases the appearance of the bacillus was morphologically typical of *B. anthracis*—a large, straight, capsulated, Gram-positive bacillus with parallel sides, clean-cut square ends, with a tendency to chain formation. As confirmed by others, there was no evidence of spore formation in the human tissue fluids.

The growth after 18 to 24 hours on the solid media invariably showed an almost pure culture of *B. anthracis*, with occasional colonies of *Staphylococcus albus* and diphtheroids. There was no evidence in any case of invasion by other pyogenic organisms. The colonies at 24 hours' growth had the typical reticulated surface with irregular wavy edges (so-called barrister's wig), producing proteolysis on the heated blood-agar medium and no haemolysis on the medium containing the fresh blood.

These colonies were subcultured, and after the organism had been isolated in pure culture the following investigations were carried out.

Morphology.—Routine films from the 24-hour culture showed the typical rod-shaped appearance of the organism in heavy interlacing chains, capsulated, and associated with the production of numerous spores. These were mainly central or subterminal, but there were many spores also lying free. The characteristic morphology was retained on repeated subculture.

Motility.—This was determined by growing the organism in a semi-solid nutrient-agar medium in a 1-in. (2.5-cm.) diameter boiling-tube. A small-bore glass tube was inserted into the boiling-tube, the *B. anthracis* being inoculated on to the surface of the agar in the small tube. The organism, being non-motile, remained localized on or just below the surface of this agar. If the organism had been an anthracoid, then owing to its motility growth would have proceeded down the small tube and eventually infiltrated the larger volume of agar outside. In all the seven strains investigated the organism was non-motile.

Proteolytic Activity.—Gelatin prepared in large boiling-tubes was inoculated as a stab culture at 24° C. The lytic effect in gelatin is a slow but definite effect. In two cases only did the organism produce the truly characteristic inverted fir-tree phenomenon. The other five strains seemed to produce little attempt at canalicular liquefaction, there being just a central core of proteolysis.

Effect of Antibiotics.—All the strains were tested for their sensitivity to penicillin and streptomycin. The usual punch-hole plate method was adopted. Table II shows the degree

TABLE II.—*Sensitivity to Antibiotics: Animal Pathogenicity*

Case No.	Strain	Sensitivity Compared with Oxford *Staph. aureus*		Death of Mouse after Inoculation
		Penicillin	Streptomycin	
1	I	25% less	Equivalent	34 hours
2	II	50% ,,	10% less	36 ,,
3	III	10% ,,	80% ,,	36 ,,
4	IV	20% ,,	10% ,,	30 ,,
6	V	25% ,,	5% ,,	20 ,,
7	VI	20% ,,	10% ,,	35 ,,
8	VII	Equal	75% ,,	30 ,,

of inhibition compared with that of the Standard Oxford *Staph. aureus*. Thus in all cases the strain was sensitive to both penicillin and streptomycin in fairly low concentrations. It is interesting to observe that on the whole the strains showed greater inhibition with streptomycin than with penicillin, using equivalent concentrations of streptomycin per ml. No production of strains resistant to these drugs was noted, as the organism was never recovered from the lesion after the patient was placed on intensive treatment. The strains on an average were sensitive to 10 units of penicillin per ml. and to 5 to 10 units of streptomycin per ml.

Animal Pathogenicity.—In the seven cases in which the organism was isolated the mouse was utilized for virulence tests. A volume of 1 ml. of a 24-hour "oxopeptone" broth culture was injected subcutaneously into the right half of the anterior abdominal wall. The animals were isolated in glass containers, the carcass, food, faeces, etc., being autoclaved after necropsy. Death occurred in all cases within 36 hours, as shown in Table II. At necropsy the local lesion was haemorrhagic, hyperaemic, and oedematous, the spleen was congested and enlarged, and on microscopical examination the oedema fluid, splenic pulp, and heart blood were found to contain enormous numbers of Gram-positive bacilli, yielding pure heavy growths of *B. anthracis* on culture.

In addition to the above investigations on individual strains, in each case a series of swabs were taken from the hair or skin of the patients in order to ascertain the presence or otherwise of *B. anthracis*. Table III summarizes the

results of these investigations, carried out before the third day of treatment (usually on the first day). Similar investigations made towards the end of the stay in hospital were negative, as were cultures made from materials taken from beneath the eschar after complete therapy.

TABLE III.—*Skin Cultures*

Case No.	2 in. Above Lesion	2 in. Below Lesion	Hair of Scalp	Right Palm	Left Palm	Right Groin	Left Groin
1	Neg.	Pos.	Pos.	Neg.	Neg.	Neg.	Neg.
2	"	Pos. A	Neg.	"	"	"	"
3	"	Neg.	"	"	"	"	"
4	"	"	"	"	"	"	"
5	"	"	"	"	"	"	"
6	"	"	"	"	"	"	"
7	"	"	"	Pos.	"	"	"
8	"	"	"	"	"	"	"

Neg. indicates only normal flora grown. Pos. indicates *B. anthracis* cultured. Pos: A indicates anthracoids cultured.

Treatment

In no case was surgery contemplated. Excision and incision, especially the murderous crucial incision which was once performed, play no part in the modern treatment of anthrax, and are probably harmful, breaking down natural barriers. A study of the literature has revealed that excision performed very early was possibly beneficial, but incision was almost invariably followed by death, and thus was much worse than no treatment at all. In this series the local lesion was covered with a dry sterile dressing and left alone after the necessary bacteriological examinations. The part was immobilized as far as possible: if on the head and neck the patient was nursed flat with the head between sandbags; if on a limb, as in Case 4, the limb was splinted. The following specific treatment was carried out (Table IV), since the literature concerning patients treated successfully with penicillin alone had not been studied when the first case was admitted.

TABLE IV.—*Treatment*

Case	N.A.B.	Serum	Penicillin (units)	Result
1	1·5 g. over 10 days	145 ml. in 4 days	650,000	Cure
2	1·05 g. in 6 days	90 ml. in 5 days	2,265,000	"
3	1·2 g. over 5 days	160 ml. in 5 days	1,344,000	"
4	1·2 g. over 8 days	240 ml. in 5 days	3,520,000	"
5	1·2 g. over 5 days	80 ml. in 2 days	2,048,000	"
6	1·2 g. over 6 days	320 ml. in 4 days	5,400,000	"
7	1·8 g. over 13 days	80 ml. in 2 days	2,800,000	"
8	1·2 g. over 6 days	420 ml. in 6 days	6,018,000	"

Neoarsphenamine.—This drug was given in two or three doses of 0.45 to 0.6 g. intravenously at five- to seven-day intervals. Doses such as these given once or twice at one- to three-day intervals have been used successfully without any other therapy (Becker, 1912a, 1912b; Pijper, 1926).

Anti-Anthrax Serum.—Until recently this has been the mainstay of treatment. Advocated by Sclavo in Italy, by Marchoux in France, and by Legge (1905) in Britain, it soon became widely used—at first in combination with surgical treatment, and later alone, with definite success. Dosage advocated differed—from 40 to 80 ml. by early workers (Legge, 1905; Lockwood and Andrewes, 1905; Bowlby and Andrewes, 1905) to 600 ml. and upwards (Hodgson, 1941; Gold, 1942). In the above series the average dosage was 190 ml. in some seven injections over four days—the total varying with the need and response of the patient. Usually between 60 and 100 ml. was given intravenously on the first day of treatment. No severe reactions were encountered during the time of serum administration, but all cases developed urticaria and pruritus on the eighth day after the start of serum therapy. This was readily controlled by the use of calamine lotion containing 1% phenol locally and "anthisan" internally, 100 mg. three times a day with meals. The serum used, apart from the first case, was that marked "War Agricultural Committee," contained in rubber-capped 500-ml. bottles. Case 1 had the product manufactured by Mulford's, and later some 90 ml. of Lister's antiserum.

Penicillin.—Several reports are now in the literature of cases of cutaneous anthrax treated successfully with penicillin alone (Murphy *et al.*, 1944; Ellingson *et al.*, 1946; Griffin *et al.*, 1948). The suggested dose increases as the years go by, starting with a total dose of 200,000 to 400,000 units advocated by Murphy *et al.*, to 5,000,000 units advocated by Griffin *et al.* The average dose used in our series was about 3,000,000 units, given usually as 64,000 units three-hourly, though occasionally as 250,000 units twice daily.

Sulphonamides.—Sulphonamides were used not as specific therapy, though claims have been made for their curative powers in anthrax by Gold (1942), but in an attempt to remove the secondary invading organisms in the lesion—usually *Staph. aureus.* The dosage was small, a total of 15 g. over 10 days being the average. In Case 4 secondary infection with a purulent discharge was very troublesome, and the patient attended as an out-patient for local and general (penicillin) therapy for some two months after the cure of the anthrax.

Case 6 presented an interesting therapeutic problem in that he had latent seropositive syphilis in addition to anthrax. On the fourth day of treatment with serum, neoarsphenamine, and penicillin, he had a pyrexia of some 101° F. (38.3° C.) lasting for eight hours; since this occurred about eight hours after the last injection of serum, the possibility of a Jarisch-Herxheimer reaction was considered. Luckily there was no focal flare-up of the syphilis—at least, it was not in evidence. A study of the literature has not revealed a similar case.

All cases have been visited since discharge from hospital. All possess a small scar which is barely noticeable. All are well, and so far none has contracted any further lesion. Second attacks are uncommon, but do occur (Inda, 1921) and are said to be mild. The two men now doing the dangerous work at tannery "A" are both discharged cases, but it is hoped that the alterations carried out at this tannery have reduced the risk of infection. A third man from tannery "A" has returned to work, but in a job connected with the further processing of the leather and not in the lime-yard. The remaining three have obtained other employment. Both men from tannery "B" have returned to work in their original occupation.

Summary

A brief survey of the sources of anthrax shows control to be applicable and useful in all but hides and skins, and a report is given of eight cases occurring in Leeds and district over a period of 14 months in persons connected with these raw materials.

The salient points concerned in the diagnosis are given, together with the details of the isolation and identification of the organism in seven cases by direct films, culture, biochemical activity, and animal inoculation.

The effect of penicillin and streptomycin on the organism is discussed, and the routine investigation of skin culture before and after treatment is cited.

Methods of treatment past and present are briefly given, and the conclusion is reached that, for all practical purposes, penicillin is probably the most desirable method to-day—from the point of view of effectiveness, time of hospital stay, expense, and unpleasant side-actions.

We wish to express our thanks to Dr. J. T. Ingram and Professor J. W. McLeod for their kind permission to publish these cases, and for their help and advice in the writing of the article; also to Miss J. Cuckston for her invaluable technical assistance.

ACUTE PERICARDITIS SIMULATING CARDIAC INFARCTION

BY

W. A. BOURNE, M.D., F.R.C.P.

Physician, Royal Sussex County Hospital, Brighton

Simulation of cardiac infarction by acute pericarditis is well recognized by cardiologists, though references are not numerous (Barnes and Burchell, 1942; Wolff, 1944). Pericarditis in such cases is of unknown aetiology, since an obvious cause would leave no doubt about the diagnosis. It forms a subgroup of the type mentioned by East and Bain (1948), in which "cause and association are quite obscure," and is termed by Peel (1947) "primary or idiopathic," by Dry (1943) "non-specific . . . from which recovery may be complete," and by Andrews *et al.* (1948) "acute idiopathic." The infrequency of specific references seems to justify a report of only two cases. The association of one with a general arterial disease suggests a possible mechanism.

Case 1

A man aged 63 was admitted to the Royal Sussex County Hospital on July 23, 1948, and was diagnosed clinically as a case of temporal arteritis. Biopsy confirmed the diagnosis and relieved a severe headache: the histological report was, "The adventitia is infiltrated with round cells, among which are a few eosinophils and giant cells. There are areas of necrosis in the media. The appearances are typical of temporal arteritis." Though the condition was regarded as still active, with persistent fever, a predominantly polymorph leucocytosis of 11,800, and an erythrocyte sedimentation rate of 31 mm. in the first hour (Wintrobe corrected, normal 0–10), discharge was necessary after a fortnight.

Headaches returned, however, and he was awaiting readmission, when in the early hours of Sept. 21 he was suddenly attacked by a pain under the left costal margin which spread to the lower substernal area. He was admitted 16 hours later, with evident severe substernal pain but negative clinical findings except for fever of 100° F. (37.8° C.) and what was regarded as triple heart rhythm. During the next 24 hours his temperature fell to normal and the pain disappeared, but a pericardial friction rub developed. An electrocardiogram showed changes indicating acute pericarditis, with elevation and deformity of the R–T interval in all leads. This returned practically to normal a fortnight later; no evidence of cardiac infarction was present. He was then discharged, afebrile, but with a raised sedimentation rate, which persisted until he was last seen in February, 1949, when he complained of pains in the occiput, sterno-mastoid, thigh, and deltoid muscles. The heart appeared normal clinically and by electrocardiography and cardioscopy.

Case 2

A man aged 37 was seen on Jan. 19, 1949. Following moderate exposure and mild malaise, and after a heavy meal, he developed epigastric pain while driving his car. This grew more severe and paroxysmal, extending from the xiphisternum upwards to the suprasternal notch, passing outwards to the pectoral regions and posteriorly to the interscapular region at the level of the sixth dorsal vertebra. Although no abnormal clinical signs of any kind were found, repeated injections of "omnopon" and pethidine were necessary.

By the next morning the patient felt practically recovered, but during this second day fever of 101° F. (38.3° C.) developed, and a loud but painless pericardial friction rub became audible. An electrocardiogram showed the changes of acute pericarditis, with elevation and deformity of the R–T interval in the limb leads and chest leads CR1 to CR7, maximal in II and CR3. Friction disappeared in 24 hours and fever in 48 hours. After a fortnight the heart was clinically and cardioscopically normal, but there was still slight elevation of the R–T interval, maximal in II and CR4. After a further seven weeks, when the patient had been working for a month, slight elevation of R–T in CR4 alone remained.

Comment

Both cases were at some stage, and with justification, diagnosed clinically as cardiac infarction. Apart from differential diagnosis, the general question of their mechanism may be raised. As will be observed from the earlier references, none has been suggested. It is also noted by Wolff (1944) that the prognosis is good, as is implicit in the terms "non-specific," "obscure," or "idiopathic" used by other authorities, since fatalities and necropsies would be likely to lead to some conclusion regarding their cause. A bacterial origin seems unlikely, since duration is brief and sequelae are rare. The cases cannot be regarded as "a chief manifestation of an infective process" (Lewis, 1946), such as acute rheumatism (Evans, 1948).

Another possibility arises, however, when the group simulating cardiac infarction is considered. The most likely simulator of a vascular lesion is another vascular lesion. In Case 1 there is evidence of activity of temporal or giant-cell arteritis, now recognized as a generalized process (Cooke *et al.*, 1946). The possibility has been suggested that this may affect the coronary vessels (Cole, 1948) or other large vessels (*B.M.J.*, 1949). A reasonable explanation of the pericarditis in Case 1 seems to be arteritis of the vessels supplying the pericardium—branches of the internal mammary vessels or descending aorta—producing a pericardial infarction. Pericarditis or subepicardial infarction is known to occur in some cases of coronary occlusion, so that vascular lesions can produce such changes. On the other hand, they are not invariable in coronary disease, so that the subepicardial muscle derives part of its blood supply from elsewhere. The vessels providing the supply may be those damaged by the arteritis in Case 1, and possibly in "idiopathic" Case 2 some chance lesion may also have affected them. The rarity of an obvious general cause may be due to the fact that when there is generalized arterial disease the coronary vessels, exposed to constant and severe stresses in unintermittent response to changes in the internal and external environment, will fail earlier than the relatively sheltered vessels of the pericardium. These, on the other hand, may suffer from such diseases of capricious local incidence as temporal arteritis.

Summary

Two cases of acute pericarditis simulating cardiac infarction are reported, one associated with temporal arteritis. Pericardial infarction is suggested as a responsible mechanism.

ADDENDUM

Since completing the above a further case has been observed and the article by Harrison and Wood (*Brit. Heart J.*, 1949, **11**, 205) has been published. Their Fig. 9 illustrates development of anastomoses via pericardial vessels in coronary artery disease, by which means the blood supply of subepicardial muscle is presumably maintained. Increase of such pericardial anastomoses by talcum insufflation of the pericardium provides a rational therapy in coronary disease and has been performed on three of my cases, without mortality and with some symptomatic relief.

Medical Memorandum

Gangrenous Intussusception

This note records the successful resection of a gangrenous ileo-ileal intussusception in an infant of just under six months, on the third day of his illness.

CASE REPORT

The following pre-operative notes were kindly supplied by Dr. Michael Cutler:

"I first saw the patient at twelve noon on a Saturday, when the mother stated he seemed 'grievy' and not his usual self. He had twice vomited, first at 9 a.m. that morning and again about 11 a.m. After the operation the mother was again questioned and agreed that the child had an attack of screaming, with drawing up of the legs and pallor, at or about the time of the vomiting. It would appear the attack was neither prolonged nor violent, as the mother, an intelligent witness, thought it unworthy of mention when first questioned.

"The first examination was completely negative, except that the child looked rather pale. The bowels had not been open since the previous evening. I attributed the pallor to a severe infection, and fully expected diarrhoea and pyrexia to appear in a few hours. I instructed the mother to give 8 fl. oz. (227 ml.) feeds of half normal strength three-hourly. I saw the child again that evening. By then he had much improved: the pallor had gone and there was no more vomiting. For the second time I sought in vain for an abdominal tumour. The child slept all through Saturday night, and by Sunday morning the mother thought he had recovered. The failure of the bowels to act was attributed to the small feeds and vomiting. I again carefully examined the patient, but could find nothing wrong. I instructed the mother to continue diluted feeds and announced that I thought the trouble was nearly over. I left the child for twenty-four hours, making my next call on Monday morning. One glance at the child as I entered the room was enough—he was sweating, pale, and obviously very ill. The mother told me he had been vomiting severely since Sunday at 9 p.m. and there was a foul odour to the vomitus. I again examined the child and found no abdominal tumour, but the other signs were now conclusive."

This is a case of intussusception unrecognized until the third day. The failure in diagnosis is attributed to absence of the usual physical sign of blood per rectum, and to the striking absence of pain after the first day. There was only one attack of screaming, and that was brief. The vomiting was not profuse until 9 p.m. on the second day. The apparent recovery early on the second day also contributed to the difficulty of diagnosis. The case exemplifies the need for vigilance, as emphasized by Morrison and Court (1948).

On admission, the child's temperature was 100.4° F. (38° C.), pulse 144, respiration 28. He looked pale and ill. The abdomen was resistant to palpation, but when the patient relaxed a firm, sausage-shaped mass could be felt lying across the right lower quadrant, fixed with the axis to the right and upwards. This mass was deep in the abdomen and did not harden with the pains. This failure to harden was explained by the subsequent finding of a gangrenous intussusception.

Operation.—Dr. A. H. Grace administered ethyl chloride and open ether. Pre-operatively a catheter was inserted into the stomach and a quantity of greenish fluid aspirated; the tube was kept in place during the operation. A right paramedian mid-abdominal incision was made, and revealed some clear free fluid. An irreducible, gangrenous intussusception of the small intestine was found. This was resected between clamps, and an end-to-end anastomosis was performed with two rows of interrupted catgut. A small oil-silk drain was inserted into the pelvis and left protruding from the wound, which was closed in layers.

The first day after operation the child was very restless, and vomited a considerable amount of green fluid. A catheter was passed into the stomach for hourly aspiration. He was passing urine normally. Intravenous glucose-saline was administered, and he was given 50,000 units of penicillin four-hourly for nine days. During this time the evening temperature reached 100–101° F. (37.8–38.3° C.). He received hypodermic injections of "nepenthe" 1 minim (0.06 ml.) as required, and 3 ml. of water hourly. On the second day after operation a quantity of stale and bright red blood was passed per rectum, and a little greenish fluid was withdrawn from the stomach. Plasma (200 ml.) was administered intravenously, followed by 200 ml. of Group O blood and normal saline.

On the third day about 200 ml. of gastric contents were withdrawn by hourly aspiration. This was a considerable increase, but the patient appeared to be much better in the afternoon. The intravenous drip was then discontinued and the bowels were opened with a rectal saline.

On the fourth day the patient was much better. Gastric suction was discontinued and he was given glucose by mouth. He was passing urine and yellow, loose motions, and he smiled for the first time since the operation.

On the fifth day he was well, and took small amounts of milk and glucose solution.

On the sixth day the wound discharged during the night. The child vomited one feed, and the bowels were opened. In the afternoon a faecal fistula formed, which closed after five days. Sulphamezathine (sulphadimidine) was given for four days, the dosage totalling 3.25 g. After this the patient became apyrexial, and his progress has since been uneventful.

Acknowledgment is due to Dr. J. McMurray for directing the post-operative treatment with untiring skill, to Dr. M. Graham, and to Sister I. A. Vincent and the nursing staff of the Royal East Sussex Hospital for their loving care, and to Mrs. W. Beaufrere for her help in the arrangement of this account.

REFERENCE

Morrison, B., and Court, D. (1948). *British Medical Journal*, **1**, 776.

Professor Frits W. Went, designer and director of the new Earhart Plant Research Laboratory in California, said that for the first time in the history of experimental biology it was now possible to grow plants under a wide variety of rigidly controllable conditions. All possible climatic factors, such as light, temperature, humidity, and gas content of the air, are simultaneously and independently controllable in the laboratory, which is to be used for experimental work by the California Institute of Technology.

Reviews

COMMON SURGICAL INFECTIONS

Clinical Aspects and Treatment of Surgical Infections. By Frank Lamont Meleney, M.D., F.A.C.S. With foreword by Allen O. Whipple, M.D. (Pp. 840; 287 figures and 241 illustrative cases. £3.) Philadelphia and London: W. B. Saunders Company. 1949.

This book is a companion to the author's treatise on surgical infections, and the two volumes form a comprehensive work. Dr. Meleney considers the commoner infections in each region of the body—the skin, the head and neck, the heart and pericardium, the mediastinum, the lungs and pleura, the peritoneum, and so on—finishing with chapters on surgical septicaemia and war wounds. The scope of the book necessitates a considerable amount of repetition, and it is difficult to read much of it at one time. It is essentially a volume of reference for the practitioner to dip into when he is confronted with a difficult case of infection in any part of the body. There will hardly be any problem on which he will not find some useful word of advice, or some illustrative case which may serve as an example of what to do or what to avoid. Every practitioner would do well to read the account of the case of appendicitis on page 417, which so strongly emphasizes that delays are dangerous.

Every section is complete in itself and provides an account of the relevant pathology and bacteriology, signs, symptoms, and treatment, and a bibliography of the most important books or articles dealing with the subject. The author shows a remarkable knowledge of the literature, particularly the American, English, Canadian, and French journals. The absence of many references to German periodicals is probably due to the dearth of original work on the subject in that country during the last ten years.

Though the book was begun twenty years ago it contains the latest work on penicillin and streptomycin, and gives an account of an antibiotic called bacitracin, on which the author has done considerable research. There is little evidence that this substance is better than or even as good as penicillin, and it does not appear that it is yet available on any scale; that being the case, it is unfortunate that the drug should be given so prominent a place in this record.

There is so much good in this book and in the companion volume that I would suggest the two were made into one small, practical manual. This would be of even greater value to the busy practitioner.

ZACHARY COPE.

PHYSICS IN SURGERY

Physics and the Surgeon. By Sir H. S. Souttar, D.M., M.Ch., F.R.C.S. (Pp. 60. 7s. 6d.) Oxford: Blackwell Scientific Publications.

It is both inherent and axiomatic that surgical, as opposed to medical, methods of treatment should be largely physical in their nature. Records show that from early times surgeons were employing splints, traction, heat, cold, and other measures the use of which demanded some acquaintance with physical principles. This tendency has increased until the present day, when the surgeon is surrounded by complicated machines in which modern physical advances are put to practical use. Furthermore, he is called upon to use radioactive materials which depend upon atomic nuclear disruption for their biological effects. The practical surgeon cannot be expected to have a detailed knowledge of the constructional features of these machines nor of the mathematical profundities of nuclear physics, but at least he should know something of the underlying general principles.

The amount of physics demanded of the medical student is not sufficient to cover this field. To remedy the defect Sir H. S. Souttar has written this small book, which explains in simple language the surgical applications of physics, from elementary levers to radioactive isotopes. The author's interest in this aspect of surgery is well known, and within sixty pages he has managed to include a wide range of authoritative information. The surgical student whose knowledge of physics is deficient or requires revision will find this book admirable for his purpose.

NORMAN C. LAKE.

EARLY DIAGNOSIS

Early Recognition of Disease. Edited by Sir Heneage Ogilvie, K.B.E., D.M., M.Ch., F.R.C.S., and William A. R. Thomson, M.D. (Pp. 134. 10s. 6d.) London: Eyre and Spottiswoode. 1949.

This is one of the handbooks in which are reproduced a series of articles published in the *Practitioner*. Two chapters have been added, one by Professor Moncrieff on diseases of childhood and the other by Professor Sorsby on diseases of the eye. The remaining articles deal with diseases of the heart, lungs, nervous system, digestive system, blood, kidneys, and endocrine glands; and with orthopaedic disabilities, non-specific arthritis in adults, malignant disease, mental disorders, and the complications of pregnancy. A wide selection in a small compass, and all written by recognized authorities.

The preface states that "during the last thirty years a mass of data has accumulated concerning the recognition of disease in its early stages. Much of this, however, has not found its way into the standard textbooks or is not easily available to the practitioner or medical student." For this reason, we are told, the book has been published. This is a reflection upon the standard textbooks and those dealing with the special branches of medicine and surgery. But is it true that these works do not contain all the important information available for the recognition of disease in the early stages? Does this small book give any information of this character which is not discussed more fully in the standard texts? Take any subject—for example, the early recognition of malignant disease of the colon. We are told in this book that it is necessary to make digital, radiographic, and sigmoidoscopic examinations. But did we not all know this before? Are not the standard books readily available to students and practitioners in the medical libraries and bookshops? These and similar questions can easily be answered by the curious reader who is willing to make the necessary comparisons.

Diagnosis is an art which must be learned at the bedside. There is no short cut to the early recognition of disease, and failure to make an early diagnosis often depends more on lack of care than on lack of knowledge, and on the neglect, or apparent inability, of the observer to select and apply special knowledge to the individual case. Professor Moncrieff has hit the nail on the head when he writes in the concluding chapter: "Complete physical examination . . . is the real clue to the early recognition of disease," and, "Skill and experience with children is an essential requisite for the early recognition of disease." And this applies to adults also.

G. E. BEAUMONT.

CLINICAL DIAGNOSIS

Diagnostik durch Sehen und Tasten. By H. Kahler. (Pp. 253; illustrated. 13s. 6d.) Vienna: Springer. 1949.

Central European medical literature has a tendency to the bizarre rather than the basic, and Dr. Kahler's book on bedside methods is therefore welcome. The author was a pupil of Chvostek, and the academic pedigree of "Diagnosis by Sight and Touch" is therefore unexceptionable. The book is arranged by regions, and under each regional heading the features to be sought or examined are enumerated.

The pages devoted to methods of examination are relatively few and are unbalanced. For example, in discussing palpation of the abdomen the author makes no mention of the everyday matter of palpation in children, but finds room for a reference to "the superficial and deep palpation of Hausmann, the diaphragmo-inspiratory palpation of Obrastzow, the double-handed gliding palpation of Martini . . . a similar procedure of Lejars and Laqueur."

There are nevertheless many features of interest among the descriptions of signs—for example, an account of the

mechanism of neck-vein pulsation. But again there are grave deficiencies. The palpation of vocal fremitus and of tracheal displacement are both unmentioned. The almost useless section on the cervical lymph-nodes does not distinguish the various groups. The book is most inadequately illustrated, and the seventeen photographs show the less common of the subjects discussed. The reader who is in a position to be critical may find some interesting gleanings. He may also be pleased to take advantage of the extensive bibliography, which gives references to many classical descriptions.

JEFFREY BOSS.

GERMAN MIDWIFERY

Lehrbuch der Geburtshilfe. By Professor Heinrich Martius. (Pp. 1,196; illustrated. M. 72.) Stuttgart: Georg Thieme. 1948.

Martius's *Textbook of Midwifery* is a typical German work, with excellent paper and print. The illustrations are adequate and good: many of them are familiar and have been copied from those already well known in Germany, and others resemble the illustrations found in De Lee and Greenhill. Professor Martius has a great reputation for ingenuity in illustrations, and the new diagrams are of the same high level as those found in his textbook on gynaecology. There are relatively few references to original papers, a disappointing omission in a volume of this quality, which will surely rival the works of Stoeckel and Guggisberg.

This review is a convenient opportunity to point out the wide divergences between German obstetrics and the practice in the United States and Great Britain. In Martius's book there is no evidence whatsoever of the influence of progress in antenatal care upon German midwifery. It is difficult to understand why German obstetricians have persistently neglected antenatal supervision and have ignored the great contributions made in the subject in this country. As a result this textbook is entirely different in style from modern British publications. Moreover, little attention is paid to the problems of the Rhesus factor, and the description of contracted pelvis is likely to be severely criticized both in the United States and in Great Britain. The book has the usual German emphasis on malformations of the foetus and upon rare deformities of the uterus. The German means of controlling post-partum haemorrhage are well illustrated, and it is interesting that the methods have never found favour here. In Germany and Central Europe Martius's book will have a wide appeal, and the author is to be congratulated on his industry and his great power of expression.

WILFRED SHAW.

IMMUNITY TO SYPHILIS

Racial Variations in Immunity to Syphilis. A Study of the Disease in the Chinese, White, and Negro Races. By Chester North Frazier and Li Hung-Chiung. (Pp. 122. 14s.) Chicago: University of Chicago Press. London: Cambridge University Press.

Both the main title and the subtitle of this little book are misleading, for little is said about true immunity, and, although the study includes Chinese, white, and nego males and females, it only refers to selected groups of the populations of Peking and Baltimore. A comparison of these three groups may, as the authors admit, be prejudiced by the fact that the Peking group were probably undernourished and short of vitamins, whereas these factors were unlikely to apply to the Baltimore groups, either white or negro. Not only are these groups compared, but the two sexes also, a matter of some importance, as it is generally agreed that syphilis is a milder disease in the white woman than in the white man. Possibly the most important point to emerge from this study is that syphilis in the male Chinese assumes very much the same pattern as it does in the white woman; this agrees with the general make-up of the Chinese people, which is more related to that of the female than the male. Of the various manifestations of the disease the Chinese are particularly susceptible to acute meningitis, to skeletal lesions, and to skin lesions in the secondary stage, but are much less prone to late neurosyphilis than the other groups. On the other hand, the negro is more commonly affected by cardiovascular syphilis, especially in the form of aneurysm. These authors consider that all the evidence is against the concept of tropism in so far as dermotropic and neurotropic strains of *Treponema pallidum* are concerned. Within its sphere the book is full of interest, but the student of syphilis would have appreciated information about more races, more areas and climates, and more forms of spirochaetal infection such as yaws, bejel, and pinta. So little is known about syphilis in China that detailed information on congenital syphilis in that country would have added much to the value of the study. There are 27 tables containing a mass of statistical detail, 13 figures, and an ample bibliography.

T. E. OSMOND.

ADVANCES IN PUBLIC HEALTH

Modern Trends in Public Health. Edited by Arthur Massey, C.B.E., M.D., D.P.A., with 23 Contributors. (Pp. 581; illustrated. £2 10s., plus 1s. 6d. postage.) London: Butterworth. 1949.

At a time when the duties of local authorities in relation to public health have been radically altered by the law, Dr. Massey has performed a valuable function in producing this useful volume. The twenty-three papers are by persons well versed in the particular aspects of preventive medicine they discuss. The objection to this form of publication is that a certain lack of balance is inevitable, and the reader must endeavour to assess the relative importance of the numerous subjects that these papers cover.

The manner in which public health must be integrated with other forms of social endeavour is laid down by Professor Crew in the section headed "Future of Social Medicine," which is contained in the chapter with the arid title, "Social Medicine as an Academic Discipline." I was disappointed, however, to find in this section no reference to family life as the basis of personality. Dr. Odlum has contributed an excellent article on the mental health aspects of public health, and W. Edwards has written an equally good discussion on the contribution of preventive medicine to general practice. Individual subjects are discussed authoritatively, as in Fraser Brockington's informative article, "Nutrition and Public Health," and Tattersall's section on tuberculosis. Tattersall rightly gives an early place to the value of B.C.G. vaccine, about which he states that "an officially sponsored supply of the vaccine is expected to be available for selected groups of patients in the near future." Professor Cruickshank's "Recent Laboratory Contributions to Public Health" is a valuable summary. Paul's account of day nurseries will, I fear, leave doubts whether the staffs of these units are always capable of carrying forward Margaret Macmillan's work.

C. O. STALLYBRASS.

SEXUAL INVERSION

The Invert and his Social Adjustment. By "Anomaly." With an introduction by R. H. Thouless, M.A., Ph.D. Second edition. (Pp. 290. 8s. 6d.) London: Baillière, Tindall and Cox. 1948.

The first half of this book is a reprint of a work published in 1927. It was widely appreciated as an authoritative discussion of the personal problems of the male invert and as a portrait of a fine man with exceptional literary gifts. The "sequel" now added records some changes of opinion and discusses broader questions such as homosexuality as an instrument of political blackmail, as a theme in literature, and as a phenomenon in prisons, internment camps, and the Services. The author is an invert (though not a medical man), and his observations now extend over nearly fifty years.

The author accepts the Roman Catholic rule that "the sex impulse can be licitly indulged only in marriage, and then only without interference with the natural physiological consequences." This does not invalidate his discussion, and the existence of other viewpoints is recognized. The author thinks that the wisest course for an invert is complete abstinence from

any form of sexual relation, even platonic. He knows that this is counsel of perfection, and thinks that legal penalties should attach only to actions corresponding to those for which normal men are punished.

The frequency of inversion has probably been exaggerated through failure to distinguish it from bisexuality, and the author estimates that the percentage of inverts in the male population is not more than five. This figure may seem high, but lower estimates may be due to lack of skill on the observer's part. The author found no evidence for the opinion that seduction plays a significant part in causing inversion—an opinion reminiscent of the attribution of tumours to trauma. Of his more recent findings, perhaps the most interesting is that sexual attraction between inverts is extremely rare: a male invert almost invariably desires that his "mate" shall be a completely normal man. The conclusion drawn is that "all psychosexual attraction is essentially heterosexual." The book leaves no doubt that sexual inversion is wholly involuntary or that most inverts—like most normal men—try to live decent and useful lives.

This work will be helpful to specialists, whose knowledge of inversion may be based solely on clinical experience. To general practitioners—and indeed to all who have to deal with young people—it will be invaluable.

RAYMOND WHITEHEAD.

DELINQUENT CHILDREN

Children in Need. By Melitta Schmideberg, M.D.(Berlin). *Introduction* by Edward Glover, M.D. (Pp. 196. 12s. 6d.) London: George Allen and Unwin. 1949.

Another book on the difficult and delinquent child seems superfluous, but this volume, by an experienced worker at the Institute for the Scientific Treatment of Delinquency, is well worthy of study. It supports the familiar theses that home is best, foster parents are better than institutions, and that institutions (if they must be used) should be small, humanitarian, and staffed by intelligent and sympathetic trained people. The author stresses that reports of committees, laws, and regulations do not necessarily achieve all that is wanted, though they may be steps in the right direction. She points out that even now there is too little recognition of the needs of individual children, and too great a tendency to move children to an institution as the easiest course. The trouble and money might be better employed improving the child's home, to which he will probably have to return eventually. Institutions are in many cases too Victorian in outlook and organization, as they were often founded by charity with the object of uplifting the lower classes and imposing a patronizing and highly religious atmosphere on the inmates.

If a child cannot be kept at home the parents can be helped and taught so that the child can return at the earliest possible moment. Earlier and more effective psychological treatment of the child is urgently necessary, and proper training—not merely laundry work and scrubbing floors—should be given to the adolescent to fit him for a worth-while job when he returns to the world.

The author has her prejudices—for example, against public schools, which she looks at too much from the neurotic child's viewpoint—but she presents her case in an interesting and persuasive way which may convince readers that, in spite of improvements and plans, all is not yet well in the management of delinquent children.

R. G. GORDON.

It is good to see the publication of French clinical lectures again. Dr. H. Grenet is already well known for his contributions in this style, and his new edition of *Conférences Cliniques de Médecine Infantile* (pp. 275; illustrated; no price; Paris: Vigot Frères; 1949) provides a good opportunity for offering a new welcome to an old friend. Fourteen lectures are included, mostly about disorders of the newborn or young infants. The cases chosen as illustrations are graphically described, and the discussions are interesting and practical. Differences from British teaching are not difficult to find—for example, the discovery of a tumour in congenital pyloric stenosis is not regarded as important. But it would be a dull world if all physicians agreed, and it is stimulating to read passages with an approach completely different from the traditional British one.

PAVLOV AND CONDITIONED REFLEXES

In the opening pages of this issue Professor E. D. Adrian describes the life and work of Ivan Petrovich Pavlov, who was born on September 14, 1849. It is perhaps not common knowledge that Pavlov was already world famous as a physiologist and the recipient of a Nobel prize for his work on the processes of digestion before he became seriously engaged in his researches on the conditioning of innate reflexes—work which was to extend his fame far beyond the physiological and even the scientific world and to become the subject of often bitter controversy among philosophers, moralists, and educationists. Professor Adrian has sketched from his own memories some of the personal qualities of this great figure. All who had met him speak of his sincerity, energy, and enthusiasm and his strenuous adherence to the truth as he saw it. Under the Tsarist regime his professional career was hampered at times by his uncompromising criticism of policies which he thought wrong. The confirmation of his appointment as professor of physiology in the Military Medical Academy at St. Petersburg in 1895 was held up for two years, largely because he made quite plain his disagreements with the Academy's Rector. After the revolution the Soviet Government, it is said owing to the personal intervention of Lenin, gave every support to Pavlov's work, but this did not deter him from voicing his disapproval of what he thought were its faults. In scientific work he was equally outspoken, but, since he applied the same thorough criticism to his own past work as to the work of others and was generous in his appreciation of sound results wherever obtained, his vehemence made few enemies. It may be that in the future more attention will be paid to some of his earlier researches and that the method of conditioning stimuli and the facts elicited therefrom will be judged more important than the behaviourist "philosophy" others have based on these experiments, but it can hardly be doubted that his work on conditioned reflexes will have a permanent place in the history of human thought.

The basic facts of the conditioned reflex are now a part of elementary biological education. All Pavlov's own work was done on dogs, and much of it with the salivatory response.[1] Food placed in the animal's mouth produced a flow of saliva (unconditioned reflex): if placing food in the mouth was constantly associated with some other stimulus, this stimulus alone would after a time cause salivation (conditioned reflex). The associated or conditioned stimulus could be a constant property of the food (for instance, its smell or appearance at a distance); something less intrinsic, such as the dish on which it was placed or the sound of that dish being filled; or it could be something quite artificial, such as the ringing of a bell or a flash of light. Pavlov's interest was directed to the study of stimuli in this last group, to which the term "conditioned reflex" generally refers. In reporting his earlier results Pavlov wrote, "We see here facts which . . . seem to imply intelligence," and for over 30 years he and his associates investigated and elaborated these facts. They insisted on the study only of observed and verifiable physiological responses to the stimuli they applied, and they denied the need for any speculation on the animal's subjective state. Pavlov himself only applied his findings to man in the most general terms, though he was hopeful that the method might bring forward useful facts for human psychology; he certainly claimed that it was one which made possible a physiological approach to "mental" phenomena.

Such an approach was clearly indicated in the study of animal behaviour and the investigation of "intelligence" in animals which was taking place at the turn of the century, particularly in the United States, where Thorndike's[2] work acted as an incentive. Moreover, it had attractions for the growing school of human psychologists who were in revolt against the arid "introspectionist" attitude and were in search of a psychology based on the study of behaviour "without the terms consciousness, mental states, mind, content, will, imagery, and the like." Both the methods and the implications of Pavlov's work appealed to J. B. Watson,[3] who, trained in the study of animal psychology, now attempted to analyse human conduct in the same way. The principles of the conditioned reflex thus became a mainstay to the behaviourism which Watson elaborated. This extremely limited conception of the springs of human conduct, which formally denies the existence of sensation, feeling, and thought because they give rise to no direct observable behaviour and then has to employ the quibble of a "verbal report" to admit them—speaking being observable behaviour—has only a very tenuous connexion with Pavlov's work. But the latter continues to possess great potentialities for the physiological analysis of adaptive behaviour. Its findings are on a different plane from those of

introspection, and it seems unnecessary to try to oppose the two. It is interesting that one of the earliest observations on conditioning was made by Twitmyer[4] on the human knee-jerk before Pavlov's main work was under way. He reported that this reflex became conditioned to a sound which would then evoke it without any stimulation of the patellar tendon. The subjects actually made "introspective reports" of the experience, and there was apparently no conscious volition or anticipation of the reflex jerk, so that in this case at any rate the conditioning must have occurred in a different part of the nervous system from that in which conscious adaptive behaviour takes place.

So far Pavlov's work seems to have less application to clinical medicine than have the results of other contemporary neurophysiological studies. The researches of Sherrington, of Adrian himself, and of many others now working along lines indicated by these pioneers frequently elucidate the problems encountered in a neurological clinic, but it is quite unusual to formulate a case in terms of conditioned reflexes; even in psychiatric practice such a formulation is rarely made in this country. The idea of conditioning stimuli, especially in the emotional sphere, is inherent in much modern psychiatry, but formal behaviourism seems on the wane. Nevertheless, the harvest of Pavlov's work will not be complete until the facts his method is still accumulating can be satisfactorily related to the physiology and anatomy of the nervous system. When that is achieved neurophysiology and neuropsychiatry will both have gained information of fundamental importance.

FREEDOM FROM WANT

Freedom from want was one of the results which President Roosevelt hoped that peace would bring. Most educated people, however, are now aware that, unless the production of food is increased at a faster rate than that of the world's population, attempts at social improvement are not likely to succeed. The elements of the problem are simple: world population is increasing at the rate of at least 20,000,000 people a year, an average of two every three seconds. The two may well become three or more as science advances, social services improve, and bodies such as the World Health Organization become fully operative. Although some areas are relatively empty, others are already overpopulated, and it is just in these areas, such as the West Indies, that the population increase is of the order of 2% per annum. If world food supplies are not progressively increased, if the growth of population is not slowed down by control of births, or if mass migration does not take place, then one or more of Nature's checks will be automatically applied in the form of famine, war, or epidemic disease. If freedom from want is to be attained, much more than the application of the natural sciences to food production will be required: superstitions, religious scruples, racial customs and prejudices—based often on the unconscious and irrational—are as important as, perhaps more important than, economics and politics.

It is not surprising that some bewilderment exists at the present time. On the one hand the Royal Commission on Population[1] has no hesitation in recommending that a replacement size of family is desirable in Great Britain, though it finds it by no means easy to weigh the factors entering into its conclusions; "imponderable" elements in the situation are at least partly responsible for this. On the other hand the example of an island such as Malta may be cited, where unless food or money is poured in from abroad or large-scale emigration is encouraged the present population cannot be supported. Many, too, will have read with some alarm such works as *Our Plundered Planet*[2] or *The Road to Survival*.[3]

In these circumstances Sir John Russell's authoritative review of the problem in his presidential address to the British Association on August 31 at Newcastle-upon-Tyne is of particular interest. Expansion of the world's food supplies depends, he believes, on extension of the food-producing areas, more intensive cultivation of the areas already used, and reduction of the present heavy wastes and losses. The food-producing areas represent at present an average per person of about one acre and a half, whereas if all the "climatically suited" areas were under cultivation there would be about five acres for every person. Agricultural science is now in a position to convert much marginal land into good farm land, and with control of pests and disease among plants and animals, destruction of weeds, and increased use of fertilizers there is every possibility of producing far more food than at present. Then, too, recent investigations have shown that only the best stock need be used for breeding. Artificial insemination from sires of good stock is now regularly practised, but there is evidence to show that fertilized ova from a particular mother can be artificially implanted into the uteri of other cows. One cow could thus become the mother of 75,000 calves. Unfortunately Sir John Russell scarcely touches on the human side of the problem, beyond the reminder that food will not be produced by the more advanced nations merely from a sense of duty. If Western standards of food are required by less advanced peoples they must also use Western standards of restraint.

[5] *Emile, ou de l'Éducation*, 1762, Paris.

Another useful contribution on this subject is a symposium of the American Association for the Advancement of Science.[4] Agricultural experts and economists have shown that by using our present cultivated lands more efficiently and by bringing certain new lands into use it would be possible to double the world's food production by 1960. This would mean that more of the red and lateritic soils of the Tropics and sub-Tropics, which together constitute 19% of the earth's surface, would have to be used. That this task is none too easy has been shown by the difficulties of growing even groundnuts and sunflowers in Tanganyika. Nevertheless in the U.S.A. the increase in rice per acre has been almost unbelievable, and an increase of only 10% in yields in China and Burma would supply food for some additional 58,000,000 people. The professor of economics at Harvard, Dr. J. D. Black, emphasizes the fact that as undeveloped communities modernize their economics their populations, while initially rising, soon begin to fall. Japan is now rapidly passing through such a cycle. However, even the rate of decrease in the birth rate of Japan is not rapid enough by itself, and the real demographic need of Asia and also of many areas in Africa and the West Indies is to devise ways by which the diffusion of the small family pattern may be quickened among peasant populations. H. R. Tolley, the Director of Economics and Statistics of FAO, puts his finger on one of the crucial difficulties: "If a particular nation needs food imports exporting countries must expand their output to meet this demand. Simultaneously the importing nation must boost its production of other goods to trade for the food it imports." Unfortunately he does not explain what other goods the African peasant, armed with a hoe, can possibly supply to exporting countries such as the U.S.A., where good imitations of everything down to a Camembert cheese are already available.

Although so far no practicable crop or cropping system has been found for restoring to the soil either the depleted nitrogen or the organic materials which are slowly but surely lost as a result of constant cultivation, nevertheless the Director-General of FAO believes that civilization can reach safety: it need not succumb in the desperate struggle of too many people trying to live on too limited resources. Prophecy is of course dangerous. Writing in 1762, at the very dawn of the industrial revolution, Jean Jacques Rousseau,[5] no foolish observer of the contemporary scene, could solemnly declare that in a few years' time Europe would be depopulated, a desert inhabited by wild beasts. In 1898 Sir William Crookes, at a meeting of the British Association in Bristol, asserted that by 1930 the world would be starving. Both these prophecies failed to come true for reasons quite unforeseen by their authors. One reason for controlled optimism is that the growth of scientific knowledge will not cease with this current fiscal or calendar year. Fungi and bacteria, for instance, synthesize not only antibiotics but vitamins and amino-acids. It may be that in the course of time the discovery will be made that if given the right encouragement they could produce something much more substantial.

PENICILLIN-RESISTANT STAPHYLOCOCCI

Although it has been known for eight years that staphylococci can be made *in vitro* to acquire a high degree of resistance to penicillin, strains possessing such resistance were very rarely encountered in patients during the earlier part of this period. They then began to be found, chiefly in patients who had undergone treatment with penicillin, and it was at first supposed that the strains concerned had acquired resistance by the same mechanism as that which had already been shown to operate *in vitro*. It was chiefly owing to the work of Spink and Ferris[1 2] that the existence of two kinds of resistant staphylococcus came to be recognized. The artificially resistant, which can be produced in the laboratory, has apparently little or no counterpart in the clinical field, and is in any case of little practical importance owing to its diminished virulence. The naturally resistant type, on the other hand, is fully virulent and owes its resistance to its property of forming penicillinase, an enzyme which destroys penicillin. It is this type which is found in patients whose treatment has failed, and is now also being encountered with increasing frequency in infections of many kinds, often before any treatment has been given.

The most definite and perturbing information about the recent behaviour of these staphylococci is that obtained by Dr. Mary Barber as the result of observations made at the Hammersmith Hospital; she found that the frequency of occurrence of such resistant strains was in three successive years 14, 38, and 59%. It seemed probable that cross-infection within the hospital accounted at least in part for this increase, and subsequent studies on out-patients have shown that among them the frequency of resistant strains is much lower. The importance of this distinction is confirmed elsewhere in this issue by Dr. G. B. Forbes, who studied strains from both in-patients and out-patients at the same hospital and showed that resistant strains were over five times as common among the former. He also found that 23 out of 50 ward nurses were nasal carriers of resistant pathogenic strains, a fact which must have an important bearing on the occurrence of infections due to such organisms. One comment which must be made on such observations is that the wearing of masks,

3 Bellamy, W. D., and Klimek, J. W., *J. Bact.*, 1948, 55, 153.

and various other precautions, some of which have been introduced or at least modified with a view to greater efficiency within the past ten years, seem not to be having all the effect they should.

A further contribution to the study of this subject by Drs. Mary Barber and J. E. M. Whitehead also appears in this issue. It is concerned with staphylococci from 100 patients, in 24 of whom resistant strains only were found and in a further 11 a mixture of resistant and sensitive strains. Again, in-patients yielded resistant organisms more often than out-patients, though the difference is much less. The findings of chief interest are those resulting from phage typing. This method of identification was applied to the pairs of cultures isolated from the 11 patients having both resistant and sensitive organisms. Though the results are incomplete owing to the fact that some cultures could not be typed, it appears that in only one patient was the phage type of both organisms the same. Still more significant are the findings when phage typing was employed not only for all the resistant strains isolated in this study but for further strains obtained in five other hospitals, 140 in all. Of these as many as 85 belonged to a single phage type and 21 to another, about five typable strains remaining which were assigned to other types. This evidence points to selection as the major factor in causing the increasing prevalence of resistant organisms; most of these, in the London area at least—so far as the hospitals where this investigation took place may be regarded as representative—belong to a single type which must originally have been rare and has flourished in a penicillin-saturated hospital environment which has tended to eliminate other and sensitive types. The possibility that resistant variants may arise by mutation cannot be excluded, and is indeed suggested by the observation that organisms of the same phage type may belong to either category, but the fact remains that such a change cannot be induced *in vitro* except at an extreme stage of habituation, when the organism has become almost unrecognizable owing to the profound changes in its morphology and metabolic behaviour.[2]

Drs. Barber and Whitehead also discuss the quantitative assessment of resistance, pointing out that the heaviness of the infection has also to be taken into account in deciding whether a given concentration of penicillin will arrest the growth of an enzyme-forming staphylococcus. Since this cannot well be determined (except perhaps by quantitative blood culture in a case of septicaemia) the practical advantage of detailed information about the organism in any given case is doubtful. The most useful conclusion to be drawn from these studies is that only a much more vigorous campaign against cross-infection can prevent the frequent occurrence of infections which may be very difficult to treat effectively.

MYXOEDEMATOUS MADNESS

Every physician of experience must be able to recall at least one instance in which he failed to recognize that a patient was suffering from myxoedema. He will be able to remember his dismay when his error was pointed out and his astonishment that such an obvious diagnosis should have eluded him. In the out-patient department it is a commonplace to see patients whose appearance clearly proclaims this malady but in whom it has been unrecognized for years. It is curious that a disease which leaves its stamp so clearly on the patient's face should pass undetected, but the truth of these assertions is once more borne out by Dr. R. Asher's paper on myxoedematous madness in this number of the *Journal*. Of his 14 patients, seen within four years, at least 9 were admitted to hospital without the diagnosis of myxoedema having been suspected.

Dr. Asher's report is naturally concerned with patients in whom mental symptoms were dominant, but his illustrations show that the characteristic myxoedematous facies was not lacking, and he has performed a useful service in drawing attention to a feature of this disease which is obviously common but not widely appreciated. The type of psychotic reaction varied: apathy, confusion, and mental retardation were the rule, but hallucinations were common, and eight patients had delusions of persecution. This inconstant pattern gives some support to the suggestion that myxoedema reveals latent psychotic potentialities and does not induce a "specific" psychosis. The paranoid characteristics have frequently been remarked in the past, and, indeed, the mental symptoms are of the same nature as those of senile deterioration. The effects of cretinism on mental development are well known, and it is the more remarkable that these aspects of myxoedema should suffer such neglect in the textbooks, even in those devoted to psychiatry. That one of Asher's patients had received the label of "paranoid psychosis" from an experienced psychiatrist may explain, but cannot excuse, the general ignorance of myxoedematous madness. The author rightly says that the fault lies in failure to recognize myxoedema rather than the psychosis which accompanies it. To remedy this defect he gives simple directions, ending with the statement, to which all will subscribe, that the only way to make the diagnosis is to know what a myxoedematous patient looks like, and the only way to learn this is to see one. He has found a raised blood cholesterol a useful guide, and the value of his "photographic test" is well illustrated in his article. All physicians will not have shared his experience of having seen cases of myxoedema with a raised basal metabolic rate.

OPHTHALMIA NEONATORUM

In papers[1,2] published in this *Journal* in 1942 and 1944 Professor Arnold Sorsby and his associates drew attention to the value of the sulphonamides in the treatment of ophthalmia neonatorum. In a series of 258 cases treated at White Oak Hospital they reported that with an initial dose of 0.25 g. over 85% were cured within eight days. With penicillin a further advance was made. In an early study in 1945 Sorsby and Hoffa[3] reported only indifferent results with penicillin eye drops in concentrations of 500,

1,000, and 1,500 units per ml., but distinctly better results —21 recoveries in a total of 22 cases—when the concentration was increased to 2,500 units per ml. The drops were instilled at half-hourly intervals for the first three hours and then at hourly intervals for 24 hours. The results as a whole were similar to those obtained with the sulphonamides. Subsequently Sorsby[4] recorded a series of 38 cases with only two failures; the treatment in this series was more intensive, the drops being instilled at intervals of 5 minutes. Clinical cure could be obtained in this way in a matter of hours, this being as great an improvement over the sulphonamides as these in turn were over the older methods. When the concentration of the penicillin was increased to 10,000 units per ml. and the frequency of instillations to one every minute for the first half-hour, the appearance of pus ceased in most cases within half an hour and clinical cure was achieved within 24 hours.[5] Massive intramuscular injections of penicillin also gave good results.

These studies established the systemic administration of sulphonamides and the local application of penicillin as alternative methods of treatment of ophthalmia neonatorum. Sulphonamide therapy has the advantage of being simpler in use, but treatment with penicillin brings about the more rapid cure. Both methods are effective not only against gonococci but against staphylococci, diphtheroids, and all the other common organisms found in ophthalmia neonatorum, and an unexpected finding was that both cured the type of ophthalmia neonatorum caused by a virus. This is important, since the gonococcus, far from being the exclusive cause of ophthalmia neonatorum, is now not even the most frequently found causal organism. Both staphylococcal and virus infections are considerably more common; Sorsby and his associates have found the gonococcus responsible for the infection in less than 20% of the cases in their recent studies. Clinically there is little to distinguish between the different varieties of ophthalmia neonatorum: all may be mild, moderate, or severe infections, and the one substantial difference is the incubation period. When caused by bacteria, the symptoms come on within the first five days of life, but with a virus infection they do not usually appear until the sixth to tenth day. In each group there may, however, be cases that do not conform to these incubation periods.[6] While the sulphonamides appear to act equally effectively on all the causative organisms, penicillin is least active in virus infections, especially if adequate concentrations are not used.

In this issue of the *Journal* Sorsby and Kane report a further study of 151 cases, the object of which was to eliminate relapses. They point out that an unsatisfactory response is not the same as a bad result: in not a single case in their experience has the response to sulphonamide and to penicillin been so poor that anxiety has arisen about the state of the eye, and some of the cases classified as relapses might well have been cases of reinfection. Their bacteriological findings confirm that ophthalmia neonatorum is caused by a number of organisms. When the initial dose of sulphonamide was increased to 0.5 g. the proportion of cases in which a clinical cure was achieved within 1–3 days rose to 68.4%; this compared with 39.3% after an initial dose of only 0.25 g. The authors were not able, however, to reduce the frequency of the relative failures, but there was some indication that with sulphamerazine, used in 24 cases, the frequency of poor responses declined. Penicillin given by mouth alone or combined with intramuscular injections proved disappointing—the results were distinctly inferior to those following intramuscular injections of large doses alone. Likewise no advantage was gained by the combined use of penicillin and sulphonamides. Further investigation is required to determine the best type of sulphonamide to use in the higher dosage now advocated, and to find a less tedious method of penicillin treatment than instillation of drops at intervals of one minute—a procedure trying both to the infant and the nurse.

There are still about 4,000 cases of ophthalmia neonatorum notified each year, and in many of them the danger of blindness is still real. That there has been a great reduction in the incidence of ophthalmia neonatorum can hardly be doubted, but the fact that of late years there has been no definite decline is a sign that existing methods of prophylaxis are unsatisfactory. The system of prophylaxis associated with the name of Credé has two components, aseptic and antiseptic.[7] Prophylaxis by antisepsis—namely, disinfection of the conjunctiva by a drop of silver nitrate—is probably of little value. On the other hand prophylaxis by asepsis—antenatal treatment of the mother by the Credé toilet to prevent infection from entering the eye of the newborn baby—is valid by present-day bacteriological concepts. The persistence of ophthalmia neonatorum therefore raises the question whether obstetricians are as alive to the possible danger of the many varieties of antenatal infection in the mother as they are to the considerably less common danger of maternal gonorrhoea. Prevailing views on the aetiology of ophthalmia neonatorum must be revised if the condition is to be eliminated.

WHOOPING-COUGH AND BRONCHIECTASIS

Bronchiectasis commonly arises during the first few years of life, the symptoms dating from an acute respiratory infection in early childhood. In the majority of such cases pulmonary collapse has occurred. It is known that when a segment of lung collapses the bronchi in that segment dilate; unless early re-expansion takes place both the collapse and the bronchiectasis become irreversible. Because of the narrow lumen of their bronchi children are more susceptible to lobar or segmental collapse than adults, and collapse occurs in such conditions as simple catarrhal bronchitis,[1] primary tuberculosis,[2] and whooping-cough. As many of these episodes of collapse are unrecognized or pass under the clinical sobriquet of "pneumonia," it is difficult to determine which diseases of childhood are the most frequent precursors of bronchiectasis, but it is widely believed that whooping-cough is the commonest cause. A history of whooping-cough is found in approximately 10% of cases of bronchiectasis in children,[3] and a slightly higher proportion is found in children with collapsed lower lobes.[4]

Although pulmonary atelectasis in whooping-cough was described in the middle of the last century,[5 6] the frequent occurrence of this complication has only recently been recognized. The main reason for this is that segmental pulmonary collapse can be diagnosed with certainty only from clear radiographs taken in both antero-posterior and lateral planes; these may be difficult to obtain in sick children, since reliance must often be placed on portable *x*-ray apparatus. In 1944 Kohn and his colleagues[7] investigated 222 children with whooping-cough by taking radiographs at weekly intervals throughout their illness. It was found that the incidence of pulmonary complications varied directly with the severity of the illness, and in 86.6% of the children considered to be seriously ill the radiographic appearances were abnormal at some stage of the disease. Most of the shadows seen on the *x*-ray films were due to collapse, the right middle lobe being most often affected, and they were usually transient. In no case was there radiological evidence of collapse caused by lymph-node enlargement—a finding which supports the current hypothesis that collapse is due to retention of viscid sputum.

More recently Nicholson[8] has reported on a series of 44 children with whooping-cough who were examined radiologically at intervals. The cases were unselected, the only criterion being that they were ill enough to be admitted to hospital. Four patients died, in three of whom collapse of the lung was demonstrated at necropsy. Nicholson found radiological evidence of segmental or lobar collapse in no less than 39 of his cases. The predisposing factor appeared to be not so much the severity of the illness as delay in admission to hospital after the onset of symptoms. Complete re-expansion of the collapsed lung took place in rather more than half the cases during the first three months of observation and in a further eight during the following six months. No re-expansion was observed after collapse had persisted for nine months. Seven children (21%) out of 33 who were followed up for more than a year had persistent collapse and probably, therefore, bronchiectasis.

This high proportion should dispel any complacency about the treatment of whooping-cough. The recognition of collapse in its early stages is of the greatest importance, for only prompt treatment is likely to be effective. Swift[9] has shown that "aerosporin" (an antibiotic produced by strains of *Bacillus aerosporus*) is of some use in pertussis provided it is given early enough in the disease, and Kinney[10] has reported that inhalations of carbon dioxide (5%) assist patients to expectorate the viscid sputum. A combination of these measures might reduce the incidence of the more serious respiratory complications of whooping-cough. Better still would be prevention of the disease altogether. The preliminary statement on whooping-cough prophylaxis issued by the Whooping-cough Immunization Committee of the Medical Research Council (appearing at page 590 in this issue) is much more encouraging than the report[11] of a trial of whooping-cough vaccine which was published in this *Journal* four years ago.

RESULTS OF COLLAPSE THERAPY

With the present shortage of nursing and domestic staff it is important that valuable sanatorium beds should be used to the best advantage. Simmonds and Martin[1] have recently attempted a statistical evaluation of the results of sanatorium treatment and collapse therapy. Their investigation is based on the study of nearly 4,000 patients discharged from Clare Hall Sanatorium in the years 1937–45. During this period the use of collapse therapy has steadily increased, and for this reason the duration of institutional treatment also increased. The figures show a steady improvement in the 3- and 5-year survival rates throughout the period. The rate for patients who had collapse therapy was surprisingly high, 70% surviving five years. On average about 7% of the patients were lost from observation.

The authors point out that, whatever the treatment, most patients with tuberculosis improve at first, and therefore studies of survival rates must cover at least five years, preferably longer, if they are to be of any value. The worker who undertakes such a long-term investigation has many difficulties. Some, like the movement and dispersal of patients, are inevitable, but others are not; among these may be mentioned the practice at many hospitals of destroying *x*-ray films. Much valuable and unique material is lost in this way, because accurate estimates of the extent of disease can be based only on radiographic evidence. It should not be difficult to arrange that the radiographs of tuberculous patients are preserved.

Simmonds and Martin are well aware of the difficulty of applying statistical methods to tuberculosis problems, but they urge that the attempt should be made so that the clinical observations of different workers may be compared. Unfortunately the Ministry of Health's classification, which they use in their investigation, lacks the precision which is needed to obtain a true comparison. For instance, the authors show that the survival rate of patients in the "T.B.+, Group 2" (B.2) category who had collapse therapy was double that of patients in the same group who had no active treatment. But the limits of this group are so wide that it can include both unilateral and bilateral cases and disease varying in extent from two zones to the whole of both lungs. Hartley, Wingfield, and Burrows[2] showed the close relationship between extent of disease and prognosis, and a classification which gives a more precise indication of the amount of lung tissue affected is badly needed. The revision of the Ministry of Health's classification[3] has left this feature unchanged. Nevertheless the Clare Hall figures show that in a selected group of tuberculous patients collapse therapy undoubtedly improves the prognosis—thus confirming Bentley's[4] observations on patients treated by artificial pneumothorax. Simmonds and Martin are fully justified in concluding that the limited resources at present available should be used for the benefit of those who can be treated with real prospect of improvement; the patients with the best claims for early admission are those with open cavitary disease in whom collapse therapy appears to be practicable.

FIRST INTERNATIONAL CONGRESS OF BIOCHEMISTRY

MEETING AT CAMBRIDGE

The first International Congress of Biochemistry, initiated by the Biochemical Society, was held in Cambridge from August 19 to 25. This Congress marks a notable stage in the development of biochemistry as a branch of science covering the ill-defined territory between chemistry and the many branches of biology. The need for an international congress on this subject has been evident for some time, and eight congresses for French-speaking biochemists have already been held since 1927.

The distinguished foreign chemists and biochemists who consented to be honorary vice-presidents, and the names of the lecturers, illustrate the international character of the Congress. Among the vice-presidents were Professor J. B. Collip, of Canada; Professor N. E. Cruz-Coke, of Chile; Academician J. O. Parnas, of the U.S.S.R.; Professor J. Roche, of France; and Dr. D. D. van Slyke, of the U.S.A. Professor M. Florkin, of Belgium, and Sir Robert Robinson, of Great Britain, were among the lecturers. The Congress was opened by the President, Professor A. C. Chibnall, F.R.S. Viscount Addison presided at a reception given to the delegates by the Government during the evening.

The discussions were held in 12 separate groups, as follows: (1) Animal Nutrition and General Metabolism; (2) Microbiological Chemistry; (3) Enzymes and Tissue Metabolism; (4) Proteins; (5) Clinical Biochemistry; (6) Structure and Synthesis of Biologically Important Substances; (7) Cytochemistry; (8) Biological Pigments, Oxygen Carriers, and Oxidizing Catalysts; (9) Hormones and Steroids; (10) Chemotherapy and Immunochemistry; (11) Plant Biochemistry; and (12) Industrial Fermentation.

Vitamin B_{12}

In a discussion on dietary factors in relation to anaemias in the Section on Animal Nutrition and General Metabolism, Dr. K. Folders (New Jersey) said that chemical research carried out with collaborative clinical tests by Dr. Randolph West, of New Jersey, discovered the properties of vitamin B_{12}. The crystals do not melt below 300° C. Emission spectrographic analysis showed the presence of cobalt; thus the molecule was a cobalt co-ordination complex. The red colour and melting point were at least in part associated with the cobalt-complex character. The significance of cobalt as an essential trace element in nutrition could be re-evaluated as the biological functions of vitamin B_{12} became known. Sources other than liver for vitamin B_{12} were being sought, since the natural vitamins were known to occur in numerous animal, plant, and microbiological materials. A red crystalline compound had been isolated from a grisein-producing strain of *Streptomyces griseus*, and this was compared with vitamin B_{12}. Comparative chemical and biological data provided evidence that the crystals from the microbiological source and vitamin B_{12} were identical.

Professor G. R. Cameron, of London, spoke on the pathological types of liver injury. He wished to reduce the complicated patterns of liver necrosis to a few simple components with a geometry of their own. Liver necrosis began with impairment in the functioning of liver cells, such cells being distributed from the trabeculae within the lobules, either singly, or in linear groups, or in clumps. At first there might be no fixed rule in grouping, but sooner or later, usually within a few hours of the onset of the phenomena, a trend of redistribution made its appearance and the necrotic area emerged as focal, zonal, diffuse lobular, or massive lesions. There was reason to believe that this grouping also represented the time sequence of necrosis. All known cases of liver necrosis produced changes which fitted into these groupings. Complications arose with variation in intensity of the causative agent, its power of self-propagation (as in infection with bacteria and viruses), and possible host variations. Analysis had to take into account the disturbances of the vascular relationships within the lobules, the action of the causative agent on the liver cells, the preservation of the biliary mechanism, and possibly the lymphatic integrity of the organ as a whole.

Adrenal Cortex

In the Section on Hormones and Steroids, Dr. G. Pincus (Massachusetts) spoke on studies of adrenal cortex function. He stated that indices of human adrenal cortex function could be obtained by measuring the urinary 17-ketosteroids and neutral reducing lipids, which appeared to vary with the secretion of adrenocortical steroid precursors. Secretory activity of the adrenal cortex was reflected in the changes in the urinary sodium, potassium, and uric acid, and in the blood lymphocytes and eosinophils. Measurements of the diurnal variations of urinary steroid excretion had been made in men and women of various ages, and it was found that the basal output of 17-ketosteroid decreased markedly in older persons, whereas the output of urinary reducing lipids did not. The diurnal variation of each changed with age. Stress procedures or the administration of adrenocorticotropin, which stimulated adrenocortical secretion, were reflected by significant changes in the various blood and urinary indices of healthy men of various ages. Response in terms of these indices to stress or to adrenocorticotropin administration occurred in psychoneurotic patients, but was absent or diminished in most schizophrenic patients. The latter were fairly responsive to adrenal cortex-extract, indicating that adrenal cortex response was largely defective in the schizophrenics. This did not appear to be a function of the nutritive state of the schizophrenic patient. The significance of derangements of pituitary-adrenal function in schizophrenia was discussed and the effects of some therapeutic procedures were presented.

It is impossible to report more than a fraction of the large number of discussions held by the Congress. The range of subjects is indicated by the 12 sections already mentioned, and the individual topics varied from a study of acetylcholine metabolism to brewing and yeast production.

During the Congress the University of Cambridge conferred honorary doctorates of science on Viscount Addison, Professor Cori (U.S.A.), Sir Charles Harington, Professor Linderström-Lang (Denmark), Professor Tiselius (Sweden), and Professor Tréfouël (France).

WHOOPING-COUGH PROPHYLAXIS

PRELIMINARY REPORT

The following preliminary statement has been issued by the Whooping-cough Immunization Committee of the Medical Research Council.

In view of the conflicting reports on the efficacy of pertussis vaccine in whooping-cough prophylaxis the Medical Research Council was asked by the Ministry of Health to investigate the problem and report on the value of prophylactic immunization against whooping-cough of children in England and Wales. As part of the investigation the Whooping-cough Immunization Committee organized a series of controlled field trials in which the experience of children inoculated with pertussis vaccine could be compared with that of control children. The results of some of the early trials have already been published (McFarlan, Topley, and Fisher, *British Medical Journal*, 1945, 2, 205). The evidence obtained suggested that the pertussis vaccine used in these trials was of no value in whooping-cough prophylaxis.

Further large-scale trials have now been carried out in collaboration with the medical officers of health of Oxford, Manchester, Tottenham, Wembley, Edmonton, Leeds, and West Ham, using a number of different vaccines of both British and American origin. Each trial was planned in a similar manner. Children, mostly between the ages of 6 and 18 months, whose parents agreed that they should take part were divided by the method of random sampling into two groups. The children in one group—the test group—were inoculated with the pertussis vaccine under trial, while those in the other group—the control group—were inoculated with an "anticatarrhal" vaccine containing no *H. pertussis*. After inoculation the

children in both groups were kept under close observation for a period of at least two years by monthly home visits made by specially appointed nurse-visitors. Those children who came into known contact with whooping-cough or who developed symptoms which might be those of early whooping-cough received special visits in order that a bacteriological diagnosis might be made. As it was essential that observers should not be influenced in their clinical assessment of the disease, efforts were made to ensure that neither the doctor, nor the nurse-visitor, nor the parents should know whether the child under observation was in the test or the control group.

Seven of the early trials, comprising a total of 4,691 test and control children, have now been in progress for over two years, and from a preliminary analysis of the results the following general conclusions may be drawn:

(*a*) In each trial the random allocation to test and control produced two equivalent groups of children, comparable in age, sex, duration of breast-feeding, size of family, and incidence of infections other than whooping-cough.

(*b*) In six of the trials the incidence and severity of whooping-cough in the test groups were appreciably less than in the control groups. In the seventh trial the results were only slightly more favourable in the test group.

(*c*) There was considerable variation in the prophylactic potency of vaccines from different sources, and there was probably also some variation in the potency of different batches of vaccine from the same source.

(*d*) One particular type of vaccine, not at present readily available, was found to give decidedly better protection against the disease than any of the others tested.

The reason for variations in the prophylactic potency of these vaccines is not clear, nor is there yet available a conclusive laboratory method of assay by which this property of a vaccine can be accurately assessed, but an investigation is in progress in which the prophylactic value in children of a number of different vaccines is being compared with their immunizing properties as shown by laboratory tests. With this aim in view trials have already been begun in Manchester, Oxford, Cardiff, Poole, Walthamstow, and Leyton.

No investigation has so far been made of the value of combined pertussis-diphtheria prophylactic, as it was considered desirable to avoid the inclusion of any factor that might complicate the issue and do nothing that might possibly harm the diphtheria immunization campaign at a stage when the true value of whooping-cough immunization was unknown. This preliminary statement has been prepared on account of the interest shown by health authorities in the outcome of these investigations. A detailed analysis is now being made and should be ready for publication early in 1950.

Members of the Committee and the medical officers of health concerned wish to record their gratitude to the many thousands of parents who have collaborated and are still collaborating in the investigation and who, when control groups have been essential, have volunteered to take part in the full knowledge that their children would not necessarily receive pertussis vaccine.

ROYAL MEDICAL BENEVOLENT FUND

In his annual report on the Royal Medical Benevolent Fund the chairman of the committee of management, Mr. R. M. Handfield-Jones, points out that the inauguration of the National Health and National Insurance schemes does not mean that the need for benevolence has ceased to exist either within the ranks of the medical profession or outside them. He gives several poignant examples of distress amongst elderly doctors and their families. During the year the income of the Fund from invested capital was £13,068, and from subscriptions and donations £23,900. A sum of £32,000 was voted in relief of poverty and distress, some of it in the form of regular annual grants to beneficiaries of many years' standing, some in the form of single grants to meet a case of illness or misfortune, and some again in the form of educational grants for doctors' children. The Fund has now a house near Wimbledon Common where 12 elderly ladies, beneficiaries of the Fund, who were previously living in loneliness are lodged in comfort. Mr. Handfield-Jones reminds the profession that the Fund has never made a public appeal; it has resisted the temptation to be "This Week's Good Cause," believing that an honourable and learned profession ought to be able to deal with its own casualties and help its lame dogs over stiles. He makes a warm acknowledgment of the continuing help of the British Medical Association through its Charities Committee and through the work of its Divisions and Branches, and also that of the Medical Insurance Agency, which "continues, as if with a touch from a magician's wand, to present the Fund with seven-year covenants which magnify the gifts twofold." The treasurer of the Fund, Dr. C. L. Batteson, points out the need for larger grants in individual cases. The former grants of £26 or £40 a year are obviously inadequate in present circumstances, and the committee is in a position to vote grants of £2, £3, or £4 a week in exceptional cases of distress. Legacies during the year totalled £21,670.

At the 113th annual meeting of the Fund Lord Webb-Johnson was elected president, and Mr. Victor Riddell honorary secretary. The address of the Fund is 1, Balliol House, Manor Fields, Putney, S.W.15.

MEDICAL DEFENCE UNION

The annual report of the council of the Medical Defence Union to its members has been distributed recently and will be considered at the annual meeting which is to be held at 49, Bedford Square, London, W.C., on Tuesday, September 20, at 3.15 p.m. The report puts forward proposals about increasing the rates of subscriptions. These increases are necessary, in the council's view, because of the considerable deficits in the Union's income and expenditure for three consecutive years, and because of the probability that these deficits are due to continuing factors and not to exceptional misfortunes unlikely to recur.

If the contention that the causes of the Medical Defence Union's unfavourable experience are likely to be permanent is a well-founded one, it may be surmised that no long period is likely to elapse before the two sister societies follow the lead of the Medical Defence Union. Meanwhile it may be noted that the increased rates are not to apply, on the council's suggestion, to new members during their first three years of membership. This is a helpful concession to junior members of the profession.

The Minister of Food has approved for publication a report containing the Food Standards Committee's recommendations for standards for processed cheese. The committee recommends: (*a*) That processed cheese be defined as cheese which has been heat-treated with or without the use of emulsifying salts, and the fat of which consists entirely of butter fat. Colouring matter may also be added. "Flavoured processed cheese means processed cheese to which a flavouring substance has been added." (*b*) That a minimum butter-fat content of 48% in the dry matter, and a maximum moisture content of 42%, be prescribed for processed cheese; that a minimum butter-fat content of 45% in the dry matter, and a maximum moisture content of 45%, be prescribed for processed cheese of the Gruyère and Emmenthal varieties. (*c*) That a maximum quantity of 3% emulsifying salts be permitted for all types of processed cheese. (*d*) That cheese spread be defined as cheese prepared to spread easily by the addition of one or more milk products, with or without the application of heat. Emulsifying salts, colouring matters, and flavouring substances may be added. "It shall have a minimum content of 45% of butter fat in the dry matter and a maximum content of 48% of moisture." (*e*) That the ingredients of cheese spread be disclosed on the labels in accordance with Article 2 of the Labelling of Food Order (S.R.O., 1946, No. 2169).

Reports of Societies

WORKING CONDITIONS IN HOT AND DEEP MINES

Empire Mining Congress

The recent Empire Mining and Metallurgical Congress at Oxford passed one of its sessions considering the physiological and psychological effects of heat and humidity in deep mines. The discussion was mainly concerned with the mines of South Africa and India, but it was pointed out that the subject was becoming increasingly relevant to British coal-mines. In India mines have reached a depth of 9,300 ft. (2,790 m.), and, although in South Africa there are no mines so far below the surface, leases have been granted which will make mining to 10,000 ft. (3,000 m.) a possibility. In Western Europe a mine of 3,000 ft. (900 m.) would be considered deep, but the subject was important here if recruitment to the mines was to be unhindered by uncomfortable underground conditions.

Dr. A. CAPLAN spoke of the psychological effects seen under conditions of high environmental temperature in the Kolar gold-fields in Bangalore, South India. The miner subjected to high temperatures, he said, suffered from mental fatigue not only during the shift but after his work was over, and in certain individuals this contributed to maladjustment and anxiety and depressive states. The men became apathetic, careless, accident-prone, and ready prey to the agitator. This view was endorsed by the superintendent of the Mysore mine on the Kolar gold-field, Mr. J. K. LINDSAY, who said that the miner of to-day would not put up with the conditions tolerated by his forebears. According to his observation the first symptom of mental fatigue in the mines was a tendency to shout, to pay undue attention to trifling incidents, and to get the work done speedily at all costs. In his experience such mental fatigue lasted longer than physical fatigue, and mental clarity was not recovered until the following day. It had been found in the Kolar gold-field that the miner could work comfortably and efficiently at wet-bulb temperatures up to 83° F. (28.3° C.); even at 85° F. (29.4° C.) the loss of efficiency was slight; it became considerable at 87° F. (30.6° C.), and at 90° F. (32.2° C.) the efficiency was down to about half the normal. One speaker said that he had paid a visit to some German mines at Hamm. When the wet-bulb temperature exceeded 82° F. (27.8° C.) in these mines the length of the shift was automatically reduced, so there was an inducement to the management to keep down working temperatures for the sake of production. Other experts declared that a wet-bulb temperature of 80° F. (26.7° C.) with a dry-bulb temperature of 90–95° F. (32.2–35° C.) and a moderate air velocity made extremely pleasant conditions in a mine, not unlike those of a summer day so far as temperature and air movement were concerned. Figures were given of the cases of heat collapse in the Kolar gold-field since the installation of cooling plants five years ago. During the five years before the plants were started the number of cases of heat collapse was 406, with two deaths; during the last five years the number has been 26, with no death.

Dr. J. S. WEINER, of the Department of Human Anatomy, Oxford, described an experiment at the City Deep mine in Johannesburg which showed that Bantu labourers—not only novices but trained men—although they had spent all their lives in a hot climate, were less able to adapt themselves to conditions in the mine than were well-acclimatized Europeans. One South African speaker said that he had obtained the views of more than 30 experienced European foremen in the Rand mines on the question of acclimatization. The majority of them agreed that acclimatization could be acquired in about 15 days; some considered that it could be acquired in a week. It was their opinion that after one to two weeks' absence from underground work there was a slight loss of acclimatization which was recovered a few days after return, but a significant loss occurred after a month's absence. About half the foremen considered that some acclimatization remained after an absence of three to six months. Cases of heat collapse occurred most frequently among men who were resuming underground work after a short remission. The co-ordination of measures to combat heat and humidity and those to combat dust presented a problem. With water used to suppress dust the wet-bulb temperature might be raised considerably, because the strata were cooled by such a process and not the air. Moreover, as coal was broken up into finer particles more heat from oxidation was generated in the dust, and this could be a serious factor in a deep coal-mine.

Nova et Vetera

ROYAL COLLEGE OF SURGEONS IN IRELAND

An Account of the Schools of Surgery. By J. D. H. Widdess, M.A. (Dublin), L.R.C.P.&S.I. Foreword by William Doolin, F.R.C.S.I. (Pp. 107. 17s. 6d.) Edinburgh: E. and S. Livingstone. 1949.

This entertaining history of the foundation and growth of the Royal College of Surgeons in Ireland and its schools gives a picture of the growth of surgery in Dublin. Surgery there followed the same general lines of development as in London and Edinburgh, with colourful touches added by the Irish temperament. The same progress can be seen from itinerant charlatanry through guilds allied with the barbers and wig-makers to a company and finally to a college.

In 1745, when the London Company of Surgeons received their charter, a society of surgeons existed in Dublin, but no systematic training was available. The foundation of the Royal College of Surgeons in Ireland in 1784, however, preceded that of the Royal College of Surgeons in London by 16 years. The Irish College has from the outset taken a lead in education, and in the first half of the nineteenth century the College held classes and conducted examinations in the preliminary sciences and in medicine as well as surgery. This responsibility was accepted by the English College only within the last quarter of a century. As in London, much of the teaching in anatomy and surgery was undertaken by private schools like the one run by the Hunter brothers in Windmill Street, but in Dublin these flourished until much later, and the last two, the Carmichael and Ledwich Schools, were incorporated in the College in 1889.

There is entertainment as well as interest in this book. In the early years of the Irish College the Dublin poor, having buried their relations with ceremony and celebrated their interment with spirit, took no further interest in the departed. The resurrection men, provided they observed a modicum of decency, were therefore able to supply the anatomists with abundant material—so abundant that the export of cadavers to England was at one time a flourishing trade, and one professor was wont to illustrate his discourses on war surgery by propping a series of subjects round the lecture theatre, firing his revolver at them, and demonstrating the lesions that resulted.

The troubled history of Ireland colours the pages. Then as now one of the chief exports of the country was medical officers for the armed Forces of the Crown. But while many served in British uniform, others were fanatical rebels. William Lawless, professor of anatomy, was expelled from the College in 1799 for treason. He joined Napoleon's army, was wounded at the battle of Dresden, and had his leg amputated by Larrey. Knowing the dangers of hospital gangrene, he mounted his horse at the end of the operation and rode off to Mainz without changing the dressings. This is a colourful book that will interest any student of the history of surgery.

HENEAGE OGILVIE.

A new international non-governmental body, the main object of which is to co-ordinate international congresses of medical sciences, was created at Brussels in April, 1949. The final establishment of this new organization was the result of much preparatory work carried out by a group of scientists under the joint sponsorship of WHO and Unesco, and it will fill the long-recognized need for a permanent organization to ensure continuity and co-ordination of medical congresses.

For Greater Protection

A MOISTURE AND
BACTERIA-PROOF PACK FOR

EVANS PENICILLIN LOZENGES

In Cartons of 20 lozenges

For some months Evans Penicillin Lozenges have been issued in a specially designed pack which has aroused great interest amongst doctors and pharmacists.

Each lozenge (500 units Penicillin Calcium Salt*) is completely sealed in a specially treated foil, which provides adequate protection against moisture and bacteria.

Full potency is assured until the moment of use.

The product name and other essential information is confined to a detachable flap which the pharmacist removes when dispensing, leaving a plain carton for the doctor's directions.

Patients can carry one or more lozenges around with them when travelling, without any fear of contamination.

SAFETY and CERTAINTY

For initial digitalisation or for maintenance, Digoxin produces the desired result quickly, safely and with certainty. Being a single crystalline glycoside of definite composition and potency, it ensures a degree of accuracy unattainable with digitalis leaf products. Orally, Digoxin is effective in a few hours; intravenously, in a matter of minutes. It is particularly suitable for maintenance in the ambulant patient because the dose may be adjusted precisely, and risk of toxic effects is reduced. 'Tabloid' brand Digoxin, 0·25 mgm.; for oral use; 'Wellcome' brand Sterile Alcoholic Solution of Digoxin (for the preparation of Injection of Digoxin).

DIGOXIN 'B.W.&CO.'

BURROUGHS WELLCOME & CO. (THE WELLCOME FOUNDATION LTD.) LONDON

The Dietary during *The Age of Growth*

AT no time, throughout the span of life, is the proper and orderly balance of the important food factors more readily disturbed than during the period of active growth and development. The food supply of every child should, therefore, contain an adequate proportion of essential nutritive elements if normal progress is to be maintained. The construction of an entirely correct dietary to suit the varying requirements of each individual is, however, beyond the possibility of realization in ordinary practice.

Many physicians ensure that the ordinary dietary of the young patient is safe and adequate by advocating the daily addition of 'Ovaltine,' which is a natural food tonic prepared from milk, eggs, malt extract, cocoa, and soya. The deliciousness of 'Ovaltine' makes it most acceptable to every child, while it is readily assimilable even by digestions impaired with disease.

Preparations and Appliances

A TRANSPARENT "PERSPEX" PERIMETER

Dr. CECIL M. RUBEN, of London, N.W.3, writes: The perimeter described below is made from a "perspex" half-sphere; the material is colourless, transparent, and about 4 mm. in thickness. The instrument has no movable parts. I have found the chief disadvantage to be the formation of troublesome reflections if care is not taken to place the head of the patient between the source of light and the point of fixation. When the source of light is a window in daylight, or an opalescent globe, so long as the general illumination of the room is good, image formation will not interfere with the test if the above

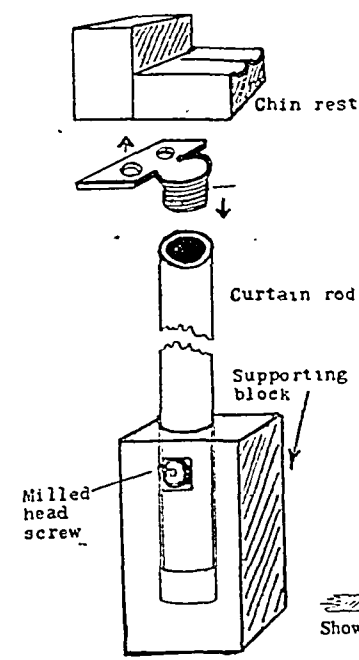
position is obtained and if only *one* source of light is used. The perimeter being transparent, the point of fixation can be placed at any distance. Best results will be obtained with a dull background.

The instrument combines the simplicity and speed of the clinical confrontation test with the accuracy of perimetry. I made the instrument for 30s. The parts required are: (1) Astral dome, ex-R.A.F., made of perspex. I bought mine at one of the stores selling ex-Service equipment for 25s.; it has a radius of 300 mm. (2) Piece of wood 18 by 9 by ½ in. (45 by 22.5 by 1.25 cm.). (3) Two metal right-angled brackets. (4) A piece of metal rod (curtain rod) 5 in. (12.5 cm.) by ½ in. (1.25 cm.) diameter. (5) Curtain-rod fitting. (6) Piece of wood 4 by 2 by 2 in. (10 by 5 by 5 cm.). (7) Black matt paint or black cloth. The dome has to be marked by scratch lines indicating the meridians 15 degrees apart and the concentric circles at 10-degree intervals. The circumferences at the periphery will be $2\pi r = 3\frac{1}{2} \times 600$ mm. $= 1{,}885\frac{5}{7}$ mm. Therefore the distance between the peripheral points will be:

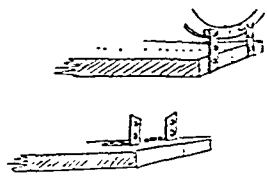
$$\frac{1{,}885\frac{5}{7}}{24} = 7.8 \text{ cm.}$$

These intervals are marked in ink on the peripheral flange and opposite points are joined with scratch lines made with a needle; care must be taken that all lines pass through the centre. (A piece of pliable cardboard about ½ in. wide by half the circumference in length is suitable as a ruler.)

The concentric markings are made with a large pair of mathematical dividers, one end being placed at the centre, the other swept around the inside surface of the dome. The distance between the circles is equivalent to

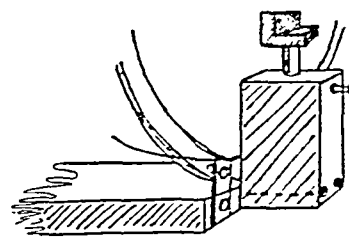


$$\frac{\pi r}{18} = 5.25 \text{ cm.}$$



The base is now taken and the metal brackets are fitted at one end equidistant from the midline; the spacing must be exact and they must be over 4 in. apart. The vertical meridian of the perimeter must be held in alignment with the central line of the base, and in this position two marks are made on the flange opposite the holes in the supporting brackets. Holes are drilled through at these marks and the dome fixed into position by nut and screw (¼ by ¼ in. (0.3 by 1.25 cm.) long). It is best if the flange just rests on the base. Surplus bracket projecting into the perimeter is sawn off.

The chin rest is made from two pieces of wood 4 by ½ by 1 in. (10 by 1.25 by 2.5 cm.), and the chin depressions are filed out. This rest is fixed to the curtain rod by the support shown, and the supporting block has a hole ½ in. in diameter drilled through its centre vertically. The fixing screw must be improvised from a nut and screw with a milled head, the nut being sunk into the wood in line with the shaft and near the top.



The centre of fixation can be made from anything suitable. My dome had a hole at the centre and my fixation point is a screw-head painted white held in position by a nut and a black rubber tap-washer. The supporting block can be screwed to the end of the base or into its top surface according to the position of the right-angled brackets. The flange is marked in indian ink with numerals ¼ in. high indicating the angle of the meridians according to the recording charts used. The concentric circles can be indicated by markings i, ii, iii, iv, v, vi, vii, corresponding to 10→80 degrees; they need not be higher than 2 mm. and only along four meridians. The base is painted black or covered with cloth. It is best to employ targets as used with screen scotometry; with a pencil in one hand and a chart held in the same hand as the target rod, or vice versa, recording is more rapid.

Another refinement is to scratch the normal limits of the field on the perimeter—a continuous line for the right field and a dotted line for the left field. This will enable the less experienced and occasional perimetrist to note departures from the normal without making a detailed recording. It is best to have the central 10-degree area bare of all scratch lines so as to assist fixation. The perspex can be polished with ordinary metal-polish and a soft cloth.

Carcinoma of the Gall-bladder

SIR,—The annotation (August 13, p. 376) suggests that a decision for or against cholecystectomy should be influenced by the possibility of carcinoma developing in a gall-bladder containing stones. As I have recently contributed to a textbook an exactly opposite view, I should like to justify myself.

When we advise an operation with an immediate mortality of at least 1–2% in order to avoid some possible disaster in the remote future, our decision is based on probabilities and we must try to make a rough arithmetical estimate. The first difficulty is to find suitable data. Statistics of gall-bladder surgery tend to be misleading, because the patients attending a large and famous hospital are a selected and unrepresentative sample. Standardized mortality rates are based on the whole population and avoid fallacies of selection; but they are open to serious criticism because of unavoidable mistakes in death certification, especially in the older age groups. The least objectional data are thus male and female death rates at ages 45–65, and several independent lines of argument suggest that the following figures from the Registrar-General's occupational mortality returns (based on the 1931 census) showing annual death rates per million living are approximately accurate:

	Ages 45–55		Ages 55–65	
	Men	Married Women	Men	Married Women
All causes of death combined	11,141	7,658	23,552	16,431
All forms of cancer combined	1,606	2,024	4,685	4,012
Gall-stones, cholecystitis, etc.	37	91	111	218
Carcinoma of the gall-bladder	10	20	42	82

If we accept your citation from Graham[1] that 8–10% of all carcinomata start in the gall-bladder we are almost driven to assume that about 90% of patients who die from gall-bladder carcinoma are falsely certified as dying from carcinoma of the stomach or colon, and that in reality the gall-bladder is one of the commonest sites of a primary cancer. Even Kirshbaum's[2] figure of 3% would create difficulty. The Registrar-General's figures fit in far better with clinical and necropsy experience.

The next question is the incidence of gall-stones at different ages in the general population. Here we are compelled to accept necropsy figures, but these are so extensive and agree so well that they should be fairly reliable. At ages over 45 at least 5% of men and 10% of women carry stones. Most authors put the figures considerably higher, but as a result of modern austerity the incidence is possibly falling.

The statistical argument now runs as follows. It is not unlikely that the association between gall-stones and carcinoma is in part due to mucosal changes producing stones, and not vice versa. But let us assume that every gall-bladder carcinoma is the result of stones and that the whole incidence of the disease falls on the group with stones. Then, in order to get the incidence of gall-bladder carcinoma in patients with stones, we must multiply the rates just given by 20 for men and by 10 for women. We can then deduce that the probability of a man dying between 45 and 55 is 1.1131 in 10 if there is no risk of gall-bladder cancer, and 1.1331 in 10 if there is a risk of gall-bladder cancer. The biggest difference occurs in women aged 55–65, where the respective risks are 1.6349 in 10 and 1.7169 in 10. Various incalculable factors might alter these risks slightly in either direction, but all my assumptions have tended to exaggerate the benefit to be gained from cholecystectomy.

Surely the reward is incommensurate with the immediate risk. The immediate risk is 1–2%, and the benefit between the ages 45 and 65 is less than 1%. A better statistical case could be made out for universal appendicectomy or gastrectomy. Life cannot be lived on the basis of sacrificing our working years for an intricate actuarial calculation of an increased expectation of life as an old-age pensioner. The decision in favour of cholecystectomy must be based on a clinical judgment of more immediate benefits.—I am, etc.,

London, E.1. DENYS A. JENNINGS.

The M.R.C.P.

SIR,—The annotation on the M.R.C.P. (August 6, p. 327) suggests that "the decision of the College is one the consequences of which it does not seem to have thought out to the end," and goes on to predict a lowering both of the status and the standard of the examination. While no one who happens already to have achieved the membership can regard lowering of its status or standards as anything but catastrophic, there is room for doubt whether the writer of the annotation is not suffering from a lack of prescience similar to that which he criticizes in the committee when he expresses the hope that in two years' time "the College will consider the possibility of holding, instead of the M.R.C.P., a primary examination, possibly in conjunction with the Royal College of Surgeons, as a preliminary to a final examination for the F.R.C.P., say four or five years after qualification."

For were this suggestion to be adopted what would be the status of the pre-1949—or even the pre-1951—Members? At present no Member can become a Fellow by examination: and I venture to predict that Members who had obtained their M.R.C.P. under the conditions which have so far prevailed would consider themselves utterly betrayed were the F.R.C.P. to be made obtainable by examination while the M.R.C.P. became obsolete or depreciated.

The procedure which would in fact become necessary if the F.R.C.P. were at some future date to be made obtainable by an examination of a standard comparable to that of the present M.R.C.P. would be to elevate all existing holders of the M.R.C.P. to the Fellowship. This would of course rob the F.R.C.P. of the special distinction which at present attaches to it as an individual honour, in that while the M.R.C.P. and the F.R.C.S. are strictly comparable, there exists no counterpart to the F.R.C.P. in the officially designated hierarchy of the Royal College of Surgeons at all. To maintain this difference in designation appears to have been the agreed policy of the Comitia to date.

To remark that "the method adopted by the Royal College of Surgeons appears to be more rational and fair" is a comment which, whether considered reasonable or not, is utterly irrelevant in the present context; for the terms of reference of the committee did not include a consideration of the desirability of equating the F.R.C.P. with the F.R.C.S., thereby lowering the status of the F.R.C.P. and abolishing the M.R.C.P. altogether. Whether this is or is not in fact desirable is beside the point as long as it is the status, standards, and function of the M.R.C.P. which are under consideration.—I am, etc.,

Boston, Mass. DAVID STAFFORD-CLARK.

Structure and Function of Muscle

SIR,—I would be glad of an opportunity to correct two misunderstandings in the report (July 16, p. 160) of a paper given to the Section of Anatomy at the Harrogate meeting of the British Medical Association.

The pattern of re-innervation of human voluntary muscle varies with the nature of the lesion in the main nerve trunk and the severity of atrophic changes in the muscle itself. Thus, after a favourable lesion such as axonotmesis, the degree of re-innervation may be normal and maturation is of a high degree, although abnormal branching is seen at the motor end-plates. Where there is scar tissue at the site of injury of the nerve some of the axons are obstructed and others may be misdirected. In such cases the intramuscular nerve trunks may contain both empty Schwann tubes and others containing nerve fibres in varying stages of maturation. Cutaneous sensory fibres fail to make functional reconnexions with the muscle. If atrophic changes in the muscle are advanced and re-innervation is delayed, the axons are seen to have left the terminal Schwann tubes, and they pass across muscle fibres in an attempt to form new connexions. If the atrophic changes are irreversible the highest degree of re-innervation is of no avail.

Fibrillation action potentials are characteristic of denervated muscle fibres—they are wholly independent of voluntary effort. One of the early signs of re-innervation of muscle is the return of motor-unit action potentials. In cases which go on to

successful recovery these motor-unit action potentials may precede probable voluntary contraction by 10 to 20 days in cases of pure axonotmesis. In cases where the nerve has been sutured or there is a lesion in continuity with considerable intraneural scar they may precede voluntary contractions by several weeks or even two to three months. The appearance of a few motor-unit action potentials is no guarantee of useful recovery; where such recovery is taking place successive electromyographic examinations of the muscle show an increasing number of motor-unit action potentials.—I am, etc.,

London, W.C.1. RUTH E. M. BOWDEN.

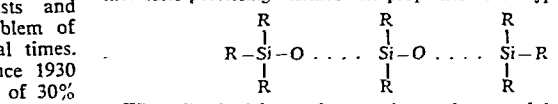
Headaches after Spinal Analgesia

SIR,—During recent discussions with anaesthetists and surgeons in this country and in America, the problem of the relief of post-spinal headaches has arisen several times. A measure which has been consistently effective since 1930 has been that of the intravenous injection of 20 ml. of 30% saline. It may aggravate the condition for 20 minutes, but at the end of half an hour the cephalalgia disappears and the ability to read and to concentrate is restored. On one or two occasions during the past 20 years it has been necessary to repeat the injection the following day, and also to combine it with placing the patient in the high Trendelenburg position for half an hour, but it has always succeeded.

It has proved equally effective in persistent post-traumatic headaches and also in those occasional ones following a diagnostic lumbar puncture. I have seen no ill effects from it beyond soreness at the point of injection when some of the salt has been inserted paravenously. Miss Joan Walker (*Brit. J. Surg.*, 1936, 24, 105) wrote on the effectiveness of hypertonic saline in raising a fallen blood pressure in spinal anaesthesia, and in a personal communication she told me that in the patients in which it had been used the incidence of post-spinal headaches was reduced.

The effectiveness of hypertonic saline for post-spinal headaches was suggested by its efficacy in the persistent cephalalgia of syphilitic basal meningitis. This remedy for insistent headache is so dependable and simple that it merits being widely known.—I am, etc.,

London, W.1. HAROLD DODD.



Silicone Pan Glazes in Bread Production

SIR,—We are concerning ourselves increasingly with the study of the possible effects of absorption and ingestion of new products of chemical origin finding their way into the baking industry. It has recently been pointed out[1] that a food which may be regarded as wholesome should make its expected contributions to human nutrition and be clean and free not only from harmful bacteria but also from substances which might be classed as chemical contaminants. The increasing number of new technological aids which are, and have been, developed for use in the growth, storage, and processing of food make it necessary for individual examination of such new products, particularly if ingested, for both acute and chronic toxicity. It is equally important to demonstrate in certain cases that usage of new materials, of which the silicones are an example, is unlikely to lead to their absorption by the product being manufactured. In such cases the information required is simpler, inasmuch as analytical procedure will suffice without recourse to the lengthy physiological examination which is necessary to demonstrate the harmlessness of materials which are absorbed and consequently ingested.

In the particular instance of silicone pan glaze it has already been shown[2] on experimental animals that this substance is very low in chronic oral toxicity. It is our view, however, that analytical evidence in a case of this type removes some of the uncertainties in translating results on experimental animals into terms of human metabolism and that problems generally of this nature require investigation by as many diverse techniques as possible.

As a result of our earlier work on the use of mineral oils in baking,[3,4] on which we based recommendations to the industry, the advent of the Mineral Oil in Food Order[5] has made the tolerances we suggested the legal limits beyond which mineral oils must not be present in foods as a result of processing. It is clear, therefore, that to attain these limits the baking industry must exercise the greatest care in using mineral oils for tin greasing or machinery lubrication, and any step which might be advised to replace the former operation would be an advantage provided the harmless nature of the replacement can be demonstrated.

For some time we have been examining the use of silicones as water-repellent glazes for bread-baking tins, these materials having been used in America and latterly on a restricted scale in this country to eliminate entirely the use of tin greases whether of edible or mineral character. The silicones are polymers containing silicon, oxygen, and alkyl radicles (R) and may be regarded as complex molecules possessing thermostable properties of the type

When dissolved in a solvent such as solvent naphtha (the inflammable nature of which probably precludes their use by many smaller bakeries unless some central distributing and processing organization can be created), these silicone solutions can be painted, sprayed, or otherwise distributed on a baking-tin and, after drying to remove the inflammable solvent, are rendered hard by baking at the usual temperature. In this way a thin durable glaze comprising a synthetic resin is created on the tin which can withstand repeated use approximately 200 times without renewal or carbonization of the coating.

We have investigated carefully the possible absorption of the resin by bread baked in silicone-coated tins and have been unable to detect by chemical means any increase in the proportion of silicon present in the crust of the loaves so obtained, irrespective of the method of application of the silicone solution to the surface of the tin. The method used was to compare the silicon content of the crust of a loaf baked in a silicone-treated tin with the content of the crust of a loaf prepared from the same dough baked in a greased tin—the crusts being treated chemically to convert any silicone present to silica, followed by colorimetric determination of the total silica in each case. In a series of comparisons no result was obtained which indicated a higher final silica content in the case of loaves baked in tins coated with the silicone resin. It should of course be borne in mind that bread naturally contains a small amount of combined silicon, hence the use of the comparative method outlined.

We have also investigated the loss in weight of a normal silicone film during a series of baking experiments, and the average loss per baking with very slight deviation was 0.0000006 g. per sq. cm., or 0.00045 g. per 2-lb. loaf tin. Even if one assumes that the entire loss is due to absorption by the loaf—which the previous experiment described indicates as unlikely—this loss would only represent a final proportion of approximately 0.00005% of silicone in the loaf, or less than 0.5 parts per million of silicon. It is possible that, as the silicone glaze is fairly easily scratched by sharp metal, stacking of the tins between bakings will cause slight removal of the coating.

In view of the data now put forward, and the earlier toxicological findings reported,[2] we do not consider that silicone pan glazes in bread production involve any potential harmful effect on the consumer and that the very small amount of silicon naturally present in bread is not materially increased by this process.—We are, etc.,

Gravitational Ulcers of the Leg

SIR,—Dr. S. T. Anning's excellent article on the aetiology of gravitational ulcers of the leg (August 27, p. 458) calls attention to a fact which is not commonly recognized—the importance of thrombosis of the deep veins as a cause of these common and disabling lesions.

I cannot help commenting on the extremely high incidence (86.6%) of deep thrombosis in Dr. Anning's cases, for, while I agree whole-heartedly that deep thrombosis is a very common causal agent, I am sure that in general it is not nearly so much

to blame as Dr. Anning's figures would suggest. Certainly in a large varicose-vein clinic attached to my service a relatively high percentage of leg ulcers are due to simple varicose veins and considerably less than half are associated with deep thrombosis. Probably the explanation is that as a dermatologist Dr. Anning does not see the majority of the varicose ulcers which are quickly and satisfactorily dealt with in the surgical clinics, while on the other hand a great many of the cases with deep thrombosis gravitate eventually to the skin clinics.

There are undoubtedly thousands of cases of gravitational ulcers of the legs receiving "dermatological" treatment both in skin clinics and from practitioners, and it is refreshing to find a dermatologist calling attention to the fact that these ulcers are a problem in hydraulics rather than dermatology, and that infection plays little or no part in their production. It is time that the profession learnt that ointments and lotions are at best useless in the treatment of these ulcers. I cannot remember seeing a gravitational ulcer during the last few years that had not been having penicillin applied as an ointment or given by injection. All too often the ointment produced a severe skin reaction.

It is good to find Dr. Anning adding his experience to that of Boyd and Robertson regarding the risk of deep thrombosis when varicose veins are injected at the same time as they are ligated at the sapheno-femoral junction. I know that many authorities on varicose veins, such as Dickson Wright and Dodd, still advocate this method. I agree that severe complications are uncommon, and I confess that for years I myself taught and wrote advising simultaneous ligation and injection—in 25 years I remember only one personal case when deep thrombosis resulted—but as a consultant to the Navy during and since the war and to the Ministry of Pensions I have seen a distressingly large number of cases where gross oedema, ulceration, etc., followed this practice.

The treatment of deep thrombosis and its complications has until recently been distressingly futile. Undoubtedly prevention is the best treatment, and the introduction of heparin and dicoumarol and a proper realization of the causes of the condition should help us to reduce the numbers of cases developing it. There will, however, always be a great many patients who will only be seen too late and who will already have developed oedema, pain, and ulceration. Surely we cannot be content to offer these patients nothing but elastic support. The problem is one not for the varicose-vein or the skin clinic alone but for them in conjunction with the radiologist and surgeon, for undoubtedly the surgical techniques of Bauer and Linton and Hardy are giving results which more than justify further consideration.—I am, etc.,

Liverpool, 1. J. B. OLDHAM.

SIR,—Dr. S. T. Anning (August 27, p. 458) concludes from a study of 270 "unselected patients" that treatment of varicose superficial veins is harmful more often than not. I should like to suggest that a high degree of selection has been achieved, as he has collected a number of cases who have had sclerosing injections without benefit, the remainder being cases of "white leg," which are obviously unsuitable for varicose-vein injection. Dr. Anning gives no figures concerning ulcers healed by injections.

My own personal impression is that the incidence of gravitational ulcer has decreased since 1929 by at least 80%. At that time no practice was complete without three or four chronic leg ulcers, whereas now ulcers are relatively rare. Some of this improvement is due to better understanding of nutrition. I have for instance seen an indolent ulcer heal after vitamin-C saturation with no other treatment, but most have required some sclerosing injections, occasionally helped by a subcutaneous ligation in our own practice.

The only chronic leg ulcers in our practice now are the really difficult cases. If the deep veins are thrombosed and the superficial veins varicose and therefore not functioning in the erect posture, the leg is perilously close to gangrene, and tight bandaging is not as a rule tolerated by the patient. There is no cure for these cases except amputation or indefinite rest in bed. They are unusual compared to the cases of ulcus cruris which heal after a few injections, or occasionally after only one. I feel that Dr. Anning has been seeing the failures and should study the successes before coming to a conclusion.—I am, etc.,

Shipley, Yorks. H. S. RUSSELL.

SIR,—The subject of gravitational ulcers is treated rather ungratefully by your annotator (August 27, p. 480)—"The many books and papers on this subject in the last 20 years have not been very fruitful"—and more realistically by Dr. S. T. Anning (p. 458). Dr. Anning deals with only one aspect of the problem—no doubt a deep-seated one—but one has to point out that, in the words of an eminent doctor, "On the black and marigolded mud the moorhen's footsteps print." (*On the Hill*, by John Masefield.)

The condition of the deep veins is important and is easy to neglect, but this problem is bound up with what one might term the "soil," and the "soil" includes "dirt," trauma, malnutrition, associated diseases, stagnation of circulation, autophytic influences, tissue inertia, and some other unknown factors. In addition to the "soil" one must consider the "seed," in other words the factor of infection. This may be staphylococcal and/or streptococcal—the "synergistic infective gangrene of skin" described by Meleney—the Vincent's organisms associated with tropical ulcer, *Corynebacterium diphtheriae*, and some others.

In addition to the "soil" and the "seed" the day-to-day and seasonal alterations in "climate" or weather have an important influence, and bodily fatigue or overwork and exhaustion must be considered. The anatomical distribution of small arteries to the superficial areas of the leg between knee and ankle, particularly the ring a few inches above the ankle, have a bearing on the formation and healing of these gravitational ulcers.

It is not the knowledge or treatment of these conditions that is defective—as hinted in your annotation—it is merely the practical application in general practice (and I do not blame general practitioners) which is defective. A short account of the factors involved in the evolution of these ulcers was published in 1945 (*Trans. R. Soc. Trop. Med. Hyg.*, 1945, 38, 259), and a method of treatment suggested, which proved not unfruitful.—I am, etc.,

Epping, Essex. FRANK MARSH.

Significance of Convulsions in Infancy

SIR,—The article by Drs. P. W. Nathan and P. M. Ransford (August 20, p. 421) presents some convincing statistics, indicating that convulsions occurring in infancy are likely to be the precursor of epilepsy. But surely the suggestion that any child having convulsions should, without careful individual study, be submitted forthwith to anticonvulsant medication is rather drastic. Repeated convulsions, it is generally agreed, are much more likely to be epileptic than those occurring singly, but, even when they are multiple, family history, possible precipitants, and the type of attack should first be considered.

It is, perhaps, not quite fair to attribute to Peterman the view that convulsions within the first two years are of no serious significance. In a later and more comprehensive communication[1] he finds birth trauma by far the commonest cause of convulsions, single or multiple, occurring in the first month of life. During the succeeding five months convulsions associated with acute infections take first place, with infantile tetany and birth trauma as less frequent causes. From 6 months to 3 years febrile convulsions still head the list, with idiopathic epilepsy, birth trauma, and tetany a good way behind. A large number of less common causes are, of course, cited. The outlook, *qua* fits, for the cases of idiopathic epilepsy and birth trauma needs no comment, but Peterman is now inclined to think that acute infection may precipitate fits only in children with a low convulsive threshold, itself evidence of a hereditary predisposition, and this he has confirmed in some cases by the E.E.G.

Margaret Lennox[2] has made a more detailed study of febrile convulsions arising in early childhood. Boys are twice as commonly affected as girls, and a family history of convulsions (not necessarily epilepsy) is found in nearly half the cases. Among

those who subsequently developed epilepsy the initial convulsion was more severe, and the incidence of birth trauma and of positive family history much higher. The clinical picture is confirmed throughout by the E.E.G., and Margaret Lennox suggests that children who have febrile convulsions should have an E.E.G. record within a week of the attack, a month later, and again at the age of 3. When indicated by clinical and E.E.G. findings anticonvulsant drugs might usefully be given up to the end of the third year. This would appear a sound policy to aim at for all cases of convulsions in early life.

It is commonly stated that the incidence of infantile convulsions is very much less than it was a generation or two ago. Is there any published evidence of this decline? There is, so far as I know, no reason to suspect any increase or decrease in the incidence of idiopathic epilepsy, and if the majority of early convulsions belong to that category we must assume that some fit-precipitants have disappeared. A fall in acute infections is unlikely, but it may be that dietary deficiencies have been made good, or that more intelligent and careful supervision of feeding has lessened alimentary upsets. Anyway, here would be a field for exploration, of especial interest, perhaps, to those who are investigating the role of metabolic factors in epilepsy.—I am, etc.,

Purley, Surrey. J. TYLOR FOX.

1 *Amer. J. Dis. Child.*, 1946, **72**, 399.
2 *Proc. Ass. Res. ment. Dis.*, 1947, 342.

SIR,—Surely Drs. P. W. Nathan and P. M. Ransford (August 20, p. 421) have reached their conclusions too easily and swiftly. They quote a series of known epileptics attending hospital and a smaller group of ordinary out-patients for a contrast. The former group was almost bound to contain a number of "items" which had some sort of fits in infancy, and the latter group is far too small, and memories even of parents are likely to be too unreliable.

I do not know what the incidence of infantile convulsions is at the present date, but I do remember that 40 years ago, when I was in general practice near here, the onset of the ice-cream season was a time when I expected to be called out of my bed fairly regularly to give hot baths, etc., to many a baby or young child who had been indulged. There were also many cases in which the exanthemata were ushered in by a convulsion. These cases never developed epilepsy, and indeed when I meet many of them now they introduce me to some buxom daughter or capable son as the man who "saved their lives" by a hot bath. Should I have kept these youngsters under sedatives (bromides, because we had no phenobarbitone) as Drs. Nathan and Ransford suggest?—I am, etc.,

Brixham, Devon. CECIL B. F. TIVY.

SIR,—May I be permitted to make some observations upon the article by Drs. P. W. Nathan and P. M. Ransford (August 20, p. 421), in which they confirm the finding of a higher incidence of infantile convulsions in epileptics than that found in the general population. In the brief space available to them there was obviously no question of a general review of the literature, but it appears to me that brevity in this case has created rather a false impression. To say without further qualification that a convulsion within the first two years of life indicates that the child is an epileptic is likely to lead to an unnecessarily gloomy prognosis that may well be hotly challenged by those with experience of convulsions in childhood.

Their figures are not remarkably different from those reported by Patrick and Levy,[1] who found 20% of infantile convulsions in 500 epileptic children and only 4% in 752 unselected controls; nor from those of Burr,[2] who found a history of convulsions in infancy in 15% of a large series of epileptics. It is difficult, however, to see how these facts alone warrant the conclusion "that convulsions within the first two years of life are to be taken as manifestations of epilepsy" and that recurrence is to be expected. Surely all that they do indicate is the well-known fact that epilepsy very frequently begins in early life and often in infancy.

The only accurate way to determine the prognosis of infantile convulsions is to follow up for an adequate period a series of infants who have had observed convulsions and see whether in fact they have any more. A most searching investigation on these lines has been published by Thom.[3] In 395 children with infantile convulsions only 12% developed epilepsy, while the incidence of epilepsy in 8,000 unselected children was 1%. From this it is fair to conclude that there is an increased chance of epilepsy in those with infantile convulsions as a whole, but, while 88% of these children remained free from further fits during the period of observation, it is scarcely legitimate to dub them all epileptic, let alone to treat them as such.

The whole argument depends obviously upon what one means by epilepsy. I have taken it that the authors have used the term in the usual sense of a chronic convulsive disorder characterized by recurrent convulsions and the strong likelihood of subsequent mental deterioration. This concept is convenient and time-honoured, even if aetiologically unsound. Nevertheless, taking this definition, it is certainly not true that most children who have an isolated convulsion at the onset of an acute infection are "epileptic." On the other hand, the convulsion appearing "out of the blue" and unaccompanied by acute illness is very much more suspect, while repeated convulsions should always be regarded as potentially epileptic.—I am, etc.,

Tuberculosis in European Voluntary Workers

SIR,—In the course of routine clinical duties among the population in an extensive and fairly representative area of the West Riding of Yorkshire I have been astonished by the number of cases of pulmonary tuberculosis which have been discovered among European voluntary workers who have immigrated to England during the past few years under the Ministry of Labour schemes.

It may well be that this finding is a mere impression on my part and one which may not be substantiated by detailed statistical investigation. Yet it is rather alarming to note that some at least of such new recruits to British industry have never had an *x*-ray examination prior to their acceptance for employment in this country, and others who claim to have had such an examination have demonstrable pulmonary infiltrations when examined within a few months of arrival in Yorkshire.

Clearly there is no room in this matter for political prejudice or parochial nationalism, but it must be borne in mind that one tuberculous E.V.W. may easily saddle the Exchequer with a bill for over £1,000 for his treatment and for the maintenance of his family during his stay in an institution and subsequent rehabilitation. The whole situation is even more perplexing when it is recalled that both the Canadian and South African Governments insist on the most rigorous health qualifications, including the production of a chest radiograph by all prospective British immigrants. Apart from the financial aspect of this problem, the further danger of introducing a new and perhaps more virulent strain of the tubercle bacillus among the indigenous population of this country may prove to be something more than mere academic speculation (see Mr. Walter Elliot's paper in the *Journal* of August 6, p. 297).

Finally, while conceding the need for additional sources of manpower in the current export drive, every effort should be made by the Ministry of Labour or the appropriate Government agency to introduce the highest possible health standards among all European workers recruited for British industry.—I am, etc.,

Halifax. BERTRAM MANN.

Torsion of Normal Fallopian Tube

SIR,—May I record a further case of torsion of an apparently normal Fallopian tube?

In June, 1947, I was called to see a woman of 48 (para 2) with severe lower abdominal pain, this being her fourth attack of similar pain in twelve months. Each attack had lasted about twelve hours. On examination, a tender swelling, estimated to be 1½ in. (3.75 cm.) in length, was palpable in the left fornix. A diagnosis of twisted ovarian cyst was made, and at operation the left tube was found to be swollen, black, and twisted on its mesosalpinx. The ovary was not involved, and there was no obvious reason for the torsion. The other tube and both ovaries were normal.

—I am, etc.,

Southampton. RAYMOND PURVIS.

Growth of Foetal Head

SIR,—I have read the letter on this subject by Dr. A. G. Murray (August 13, p. 387). Like the late R. E. Roberts, I have estimated foetal maturity on the assumption that the foetal skull grows at a constant rate during the last month of pregnancy. I have probably made over a thousand of these examinations since Reece[1] described his method in 1935, and my impression that this method is of definite value has gained strength through successive years—particularly so in the last six hundred cases, in which the proved accuracy of the vertical shift technique[2] has contributed to the precise measurement of Reece's greatest circular section. Reece based his calculations of foetal maturity on the work of Calkin, who showed that the diameters of the head are proportional to the length of the foetus.

Proof of growth in the last month is difficult if cephalometric results are not accepted as reliable evidence. Clinical measurements immediately after birth are apt to be upset by moulding. If the foetal head does not grow during the last month cephalometry at the 36th and 40th weeks would give similar results. This is not so in my experience. The greatest circular section will have increased by about four-tenths of an inch (1 cm.).—I am, etc.,

Haemorrhage into the Spermatic Cord

SIR,—The following case was erroneously diagnosed as a strangulated hernia by two independent doctors of experience.

On April 26, 1949, a boy aged 13 was playing football and, while running, he became aware of a slight pain in the left groin not associated with any injury at all. During the next five minutes the pain increased in intensity until it became fairly severe but not excruciating. He cannot remember whether he ran about or remained still during the time when the pain became more severe. At this time he noticed that a lump had developed in the groin.

After an hour the pain diminished gradually and he was able to sleep that night, but was aware of the pain on awaking next morning. His doctor was called and, finding a tender irreducible lump with no impulse on coughing, he diagnosed a strangulated hernia and sent the patient into hospital with a letter which read, "Though not appearing typically like a hernia I think it is one." This diagnosis was substantiated by the doctor who saw the boy on admission to hospital.

At operation on the next day (April 28) the lump was found to be due to swelling of the spermatic cord, which was black in colour throughout its length. Torsion of the testicle was suspected and the tunica vaginalis opened, but the testicle and epididymis were seen to be quite normal. The coverings of the spermatic cord were then divided and the entire cord was found to be infiltrated with blood clot. This was gently swabbed away with dry gauze, but the bleeding point had evidently sealed and was not discovered. There was no hernial sac. The wound healed by primary union and recovery was uneventful.

Evidently this condition can simulate a hernia on clinical examination and can cause the surgeon to suspect a torsion of the testicle at operation. It should be borne in mind in the differential diagnosis of surgical emergencies of the inguinal region.—I am, etc.,

Boston, Lincs. CHARLES MACLAY.

Stress Incontinence in the Female

SIR,—I have followed the correspondence on this subject with interest. So far none of your correspondents has pointed out that this condition may be a neurotic manifestation simply and solely, due to neither anatomical nor organic neurological causes. To attempt to cure such a case by any form of operation would be as likely to be followed by permanent cure as an attempt by a thoracic surgeon to cure the air swallower by slinging up the oesophagus.

Non-realization of this may lead to one of the most worthwhile operative procedures, the cure of stress incontinence, coming into unwarranted disrepute.—I am, etc.,

East Boldon, Co. Durham. TERENCE G. ROBINSON.

Dermographia

SIR,—A case of dermographia came under my care recently, and the following particulars may interest your readers.

The patient, a nurse, consulted me on December 16, 1948, suffering from dermographia which she had had for several months. Her skin was extremely sensitive to the touch—a thumb-nail drawn lightly over the surface causing a weal to come up almost immediately. The weal took about five minutes to come up, during which time intense pain was experienced, but this passed off as soon as the weal was fully formed. Such simple movements as crossing her legs, combing her hair, or even lying in bed caused these weals to come up. In consequence of this she was becoming very debilitated and nervous. She found hot baths relieved the pain, although the friction of the towel while drying herself again aggravated her condition.

She had previously had desensitization tests, which proved negative. This was followed by a course of peptones and later by typhoid shock treatment, neither of which gave her any relief. She was then put on a milk diet with calcium injections and hydrochloric acid by mouth, without result. While under this treatment in hospital she lost a stone (6.3 kg.) in weight. After a period of four months there was no improvement. One of her fingers became infected, and she was treated with penicillin. The result of this was a further aggravation of her condition. It was at this stage that she consulted me.

A radiograph of her chest was negative. The only possible focus of infection which could be found were her tonsils, which were enlarged and pitted but which had been passed as satisfactory during the time she had been in hospital. With a view to improving her general health and sedating her nerves I decided to try to build up her general condition by a simple tonic containing lime, phosphorus, and iron, phenobarbitone gr. ½ (32 mg.) t.d.s., and general ultra-violet-light treatment. She had six general ultra-violet-light treatments before the end of the year, and these then stopped for five weeks. She received them again every other day in February for nearly four weeks, and she had a further three treatments in the middle of March. On April 1 she reported that she still had a very little dermographia, but there was no further burning and her general condition had improved considerably.

On further consultation with a nose-and-throat specialist her tonsils were removed as being a possible focus of infection, and early in May she had returned to full duty in hospital (being a sister in charge of a ward) completely relieved of her symptoms.

This case is interesting, demonstrating as it does the remarkable effect of ultra-violet light on this condition, which had resisted various forms of treatment. In addition it is important in such cases to make sure that any doubtful focus of infection is eradicated.—I am, etc.,

Christchurch, New Zealand. W. GORDON RICH.

Production of Dental Caries

SIR,—I was most interested in the article by Dr. P. Pincus on the production of dental caries (August 13, p. 358), and I found his logical reasoning as he took it step by step, smashing the lactic acid theory on the way, quite fascinating. While appreciating the considerable research he has done in this con-

AN ADVANCE IN PENICILLIN THERAPY

'AVLOPROCIL'

PROCAINE PENICILLIN 'G' OILY INJECTION

(with 2% Aluminium Stearate)

'Avloprocil' contains the procaine salt of Crystalline Penicillin in oily suspension and offers important advantages to both doctor and patient:—

Therapeutic blood levels of penicillin maintained for 36-48 hours or longer

Effective penicillin therapy achieved with a single daily injection

Administration comparatively free from irritation and pain

10 c.c. vials (300,000 units of penicillin per c.c.) Singly and in boxes of 5

LAWS OF MEDICINE

Weigert's Law

"That the degree of reparation of injured tissue exceeds the demand"

KARL WEIGERT

KARL WEIGERT (1843-1905) *was a pathologist and bacteriologist, and Director of the Institute of Anatomy and Pathology at Frankfurt.*

If a Green Lizard injures its tail, it will grow two or even three more, simultaneously. Such lavishness is often shown by nature in order to 'make assurance double sure.'

Similarly in the quest for new synthetic substances of therapeutic value, research chemists often prepare and test several hundred compounds during the preliminary stages alone.

The pharmacological teams at Boots recognise this and accept it as part of their exacting work. They are satisfied if, after preparing thousands of new substances, one is eventually found to be of service to the medical profession.

Detecting Deficiency

'BEPLEX' Elixir is available in bottles of 4 oz.

'BEPLEX' Capsules are available in bottles of 50.

Each c.c. of Elixir contains: Thiamin Hydrochlor. ·125 mg. Riboflavin ·250 mg. Niacin 1·250 mg. Pyridoxine Hydrochlor ·125 mg. *d*-pantothenic acid ·625 mg. and other B-complex factors.

EARLIEST symptoms of vitamin B-complex deficiency are often difficult to detect without exhaustive and far-reaching tests. Where B-avitaminosis is suspected, for example, when the patient complains of "not feeling well" but is unable to be more specific, administration of total B-complex as provided in 'BEPLEX' is indicated. 'BEPLEX' is available in two forms, the Elixir which is a palatable aqueous extract of rice bran, and Capsules which contain concentrated yeast extract. These provide in a convenient and complete form all the elements of the B-complex.

20 years, strengthening with the passing of time; and with it came an ever-increasing appreciation of his influence in public health. So intuitive was his selection of staff, so inspiring and encouraging was his leadership, and so practically sound was the training he gave them that many of his young men now occupy high positions in the public health service. He was loved and respected by them all, and later they often turned to him for guidance and help that was never refused. Ferguson came to Surrey from Lancashire in 1929 to take over from Professor E. W. Hope, of Liverpool, who had been acting county medical officer. Those were difficult days in the [illegible] in Surrey. Two main influences [illegible] problems—the transfer of Poor [illegible]nty Council with the consequent [illegible] hospital service, and the rapidly [illegible] the need to develop the existing [illegible] threw himself whole-heartedly [illegible] difficulties; and, with his capacity [illegible] the problem to its simplest form, [illegible]ence in Lancashire, his unspar[illegible]nce which an enlightened county [illegible]cil had [illegible] unty health services were slowly built up t[illegible] st in the country. Ferguson's reputatio[illegible]c health was established and the inevitabl[illegible] as a first choice for innumerable committee[illegible] affairs; indeed, no such committee was com[illegible]ticularly those concerned with hospitals, without the name of Ferguson of Surrey. A catalogue of the committees on which he gave such valuable advice and guidance would be too lengthy to include here. But his help was also sought by examining bodies for the D.P.H.: he was examiner for London and Manchester Universities and for the English Conjoint Board.

One project to which Ferguson gave much effort was the development of the health services of the great L.C.C. housing estate at St. Helier. The provision of a first-class school health service, a health centre for the local preventive services, and a new hospital were only parts of that scheme. In particular, he was justly proud of St. Helier Hospital. Tribute has been paid in naming the nurses' home of that hospital "Ferguson House." He was proud, too, when he was made an Honorary Physician to the King in 1941; he felt it was one of the highest honours in the profession—and it was richly deserved. Later he was to receive further recognition in 1946, when he was created a C.B.E. But his greatest satisfaction came from the knowledge that he had been the architect of the efficient and extensive health services of the county which he served so well. So highly was Ferguson's knowledge, experience, [illegible] administrative ability appreciated that he was not [illegible]ed to retire at the end of his service in Surrey. He was [illegible] a temporary appointment as a principal medical [illegible]e Ministry of Health: he accepted and, with the [illegible]ndation from those whom he served there, he therapeutic properties his best. Unfortunately, the last two [illegible] now being used on an enormous by an insidious illness which [illegible] with the sentence: "The task of those few, if any, knew that many precious dollars to spend on this he should worry his [illegible] to distribute such supplies as reach before the end it was [illegible] easy one." [illegible] d to the inevitable.

The inference appears to be that t[illegible]otional moment not available in this country is limited to son[illegible] available for its purchase. If this infer[illegible] seems a most opportune time to express leave a gap in many of this and other life-saving drugs will shed, and his wide from the effects of sterling-dollar crises uson, his daughter, of medical ideas and information.—I am, r deepest sympathy

Rostrevor, Co. Down.

Dr. F. Hall writes: News of the death of James Ferguson was received with great regret by his friends and former colleagues in Lancashire, where he spent the earlier part of his public health career. From 1920 until his appointment as county medical officer for Surrey he occupied the post of chief assistant medical officer to the Lancashire County Council, a period during which the health services of that county were actively developed. Intellectually brilliant and endowed with a clear and constructive mind, Ferguson exercised an important influence on this process and helped to lay the sound foundations upon which the services were built. Those of us who were in the service at that time will long remember not only his friendly and helpful counsel but also his thoughtful and discerning views upon major social and health problems. Large numbers of the more unfortunate members of the community he served, particularly the blind and crippled children, also owe him a debt of gratitude for the thorough and sympathetic manner in which he exercised his administrative functions in arranging for their welfare. The public health services and the medical profession have lost an honoured and valued member, one who at all times maintained the highest ethical standards of medicine in all its varied relations.

W. T. WARWICK, M.B., F.R.C.S.

Sir Gordon Gordon-Taylor writes: Some years ago I wrote of a distinguished Australian surgeon that he was "a man of few words, a flair for diagnosis, and a sharp knife": these words would not inaptly describe my old friend and colleague, Turner Warwick, with the substitution of the terms "careful" and "deliberate" for "sharp." Warwick, whose obituary notice was printed in the *Journal* of September 3 (p. 549), was never an architect of talk, not that he was unready to take part in any discussion that was for the benefit of his patient or on a subject upon which he entertained strong views, but he was not publicly disputatious, and I imagine that he felt the strain each time he was compelled to participate in open debate. His diagnostic flair was extraordinary: he was the first, or at least one of the first, to make the diagnosis of a ruptured oesophagus; he tentatively formulated the startling diagnosis of actinomycosis of the rectum in a patient of the writer's, subsequently confirming its accuracy by demonstrating the streptothrix fungus on numerous occasions before the patient's death; he unerringly diagnosed a haemorrhage into an intrathoracic goitre in a colleague, when all others in consultation took the most sinister view of the case; it is even alleged that he suspected the rare affection which terminated his own life.

His work and outlook bore the impress of his distinguished senior colleague, William Sampson Handley, and this contact, together with the years of nurture in the Bland-Sutton Institute of Pathology, perhaps inculcated in him a livelier Lucretian interest in the nature and cause of things than in the technical correction or ablation of human affections and ills, perchance sustained by Cromwell's hope: "To be a seeker is to be of the best sect next to a Finder, and such an one shall every faithful, humble seeker be at the end."

He was the "whitest" man that ever lived, "foursquare," of transparent honesty, completely devoid of self-seeking, unsparing of effort on behalf of others. Perhaps the affection in which Warwick was held may be summed up in words used of the old St. George's surgeon, Sir Prescott Hewett, who also owned a Doncaster background: "Few men were more beloved by those who were connected with him in practice, whether as pupils or patients, for he was a man 'who would not merely scorn

a base action, but with whom anything base would be inconceivable.'" The idea of any panegyric would have been abhorrent to a nature like Turner Warwick's, but I believe that he would have liked a senior colleague to say of him that throughout life he always played the game. He did.

Dr. WINIFRED PEACEY, who died in April last, was an outstanding figure in the West of England. After studying at Oxford and the London School of Medicine for Women she qualified in 1921. Her father was an Anglican canon, and she was the only Catholic in her family. Two of her sisters became Anglican nuns and several of her brothers became Anglican clergymen. After holding a house appointment she joined the Congregation of the Daughters of the Cross and was appointed to their convent at St. Michael's Hospital, Hayle, Cornwall, in 1925. From then until her death Sister Marie Theresa, as she became, worked unceasingly. During her long term of office as medical superintendent the facilities of the hospital were extended and it became more and more an important link in the chain of hospitals in that area. Sister Marie Theresa became one of the best-known and most dearly loved doctors in the district. The hospital, at first staffed by general practitioners in the neighbourhood, grew under her guidance, and over the last ten years treated nearly all the emergency cases from the surrounding districts of Hayle, St. Ives, and the rural area covering the wild Cornish coast and countryside down to the Lizard and Penzance. Sister Marie Theresa, apart from acting as superintendent, was also responsible for radiography and for most of the anaesthetics administered. Three or four years ago she estimated that she had given 16,000 anaesthetics for all types of cases with only one death on the table. She participated fully in the religious life of the convent, gave lectures to the nurses, and supervised the busy physiotherapy out-patient department. Although a nun, she spoke her mind on all occasions, and it was her forthright character which endeared her to those who understood her and appreciated her great qualities. In common with the other members of her sisterhood she scarcely ever left the hospital or convent grounds, but nevertheless she knew every family in the district and conducted the business affairs of the hospital with precision and impartiality. Thanks to her firm and fair management of the hospital there was never any friction among the medical staff of specialists and practitioners, and her ruling was always accepted as final. During the 10 years which I spent in surgical work at the hospital I came more and more to depend on her sound judgment in clinical matters. Over many long hours of operating by day or night one came to rely on her impassive moral support from the "top of the table" and to bow to her cryptic remarks when surgical zeal began to outrun discretion. Sister Marie Theresa was never disturbed by the most irritable surgeon or by the most unreasonable and exacting patient. Few doctors have devoted themselves more whole-heartedly to their profession and looked less for reward or recognition. Her long illness failed to dim her spirit, and she continued to work until the spread of metastases prevented her from walking. It is the greatest satisfaction to all who knew her that she lived to see her hospital saved from State ownership, concerning which she had strong views seldom heard, I imagine, from the lips of one who had chosen the convent for her life's work.—E. C. A.

Dr. GWILYM JAMES, of Aberystwyth, died suddenly on June 24. The son of a sea captain of Aberystwyth, Gwilym James first attempted to follow his father's profession, and he served for a period as apprentice in a sailing ship. Later, however, he studied medicine at St. John's College, Cambridge, and at University College Hospital, where he qualified in 1911. He was a house-surgeon at the Queen's Hospital for Children, Bethnal Green, and also held resident appointments at the Royal Northern Hospital. He settled in general practice in Llanelly in partnership with Dr. Samuel Williams. Here over many years Dr. James won the esteem and affection of his patients by his outstanding ability and his self-sacrificing devotion to his work. He served as a captain, R.A.M.C., with the 2nd Railway Construction Section of the Royal Engineers throughout the 1914-18 war. At Llanelly he was in practice from 1919-43, and he was also honorary consulting surgeon to the Llanelly General Hospital. Ill health compelled his retirement six years ago, and since then he had been living at Aberystwyth, where he renewed many old friendships.

Dr. ARTHUR CARVETH JOHNSON died on June 28 at the age of 63. He was born in West Norwood, London, of Cornish ancestry, and was educated at the Merchant Taylors' School, where he won a scholarship to Downing College, Cambridge, and to St. Thomas's Hospital. He graduated in 1913, and after holding house appointments at St. Thomas's and at the Brompton Hospital he joined the Welsh National Memorial Association for Tuberculosis. He was at first responsible for the districts of Brecon and Radnor, and was transferred to Newport in 1917. Dr. Johnson played rugby for his school and for his hospital. He was a well-known breeder, exhibitor, and judge of bull-terriers, and was a life-member of the Bull-terrier Club. He was at one time chairman of the Newport Canine Society and president of the Newport, Devon, and Cornwall Society. A keep photographer, he was a founder member of the Newport Camera Club, and was its president when he died. At the age of 21 Dr. Johnson was initiated a Freemason, and at the time of his death he was provincial grand senior warden for the province of South Wales, Eastern Division. He was a member of the Newport Medical Society, and he had been in charge of the tuberculosis services for practically the whole of Monmouthshire for many years. He was considered to be an authority on his subject, and his opinion was valued throughout Wales. Dr. Johnson was twice married, and he is survived by a widow and three children.—J. T. R.-E.

Dr. ALEXANDER SCOTT died at his home in Sileby, Leicestershire, on August 16 at the early age of 50. A student of St. Andrews, he graduated M.B., Ch.B. in 1928 and held resident house appointments at the Dundee Royal Infirmary. He had been deputy medical superintendent of Baguley Sanatorium and an assistant tuberculosis officer in Sheffield.

E. K. M. writes: Dr. Scott came to Leicester as senior tuberculosis officer in 1945. His experience of his subject was great, but it is more of his character as a man of which I would write. Following, as he did, a man who had given the last thirty years of his professional life to the work of the local tuberculosis clinic was not particularly easy, but Scott soon endeared himself to the staff and even more especially to his patients. He was a man of great courage and full of life to a remarkable degree. It may be said that he had a zest for living, everything—his profession, his garden, his bee-keeping—his very special hobbies—was so intensely interesting to him. His death was marked by more than one letter in the local press from former patients expressing their lifelong gratitude for the words of cheerful hope which he had been able to give them. Scott leaves behind him a widow and four young children.

Dr. JAMES ANDREW GIBSON died on August 19 at his home in Lancaster. A student of Edinburgh University, he graduated M.B., C.M. in 1895, proceeding M.D. in 1900. After being in general practice at Kendal, he came to Lancaster in 1898. In 1908 he joined the staff of the Royal Lancaster Infirmary, and was in charge of the electro-medical department. He was largely responsible in those early years for the introduction of the first *x*-ray unit to be installed there. He was appointed honorary medical officer to the infirmary in 1911, and was a member of the general committee from that time onwards. Dr. Gibson took a large share in the planning of the original extension of the hospital buildings, and he was elected president of the Royal Infirmary in 1927 and 1928, and again in 1942. He was chairman of the house committee for many years, both before and after his retirement from general practice, and was chairman of the medical committee from 1931 to 1938. He was elected honorary consulting physician in 1939, and he acted as chairman of the local medical war committee during the recent war. Over the past 50 years, while he lived in Lancaster, Dr. Gibson built up a large and flourishing general practice, and for many years was in partnership with Alderman P. F. Mannix. He was much beloved by all his patients, and with

his quiet and assured manner he was a great comfort to many who sought his help. To a few of his more intimate associates his generosity and kindness to the poor and needy were well known. By his professional colleagues he was respected and admired, and his wise counsel and unhurried, unbiased judgment in controversial matters was of inestimable value in the administration of hospital affairs. His colleagues all regretted that during his latter years failing health prevented him from continuing to guide the affairs of the infirmary whose welfare and smooth running were always his first and most important interest. His loss is a great one to all those who knew him, and his memory will be cherished. He was a man of sterling quality, unimpeachable integrity, and a loyal and beloved friend.

Medico-Legal

PARTIAL INTERCOURSE AS CRUELTY

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

Cruelty for divorce purposes is nowhere defined by statute, but the accepted traditional definition is, briefly, conduct endangering or threatening the spouse's life or health. The idea has been gradually clarified by successive decisions of the courts, but each case is decided on its own facts. One of the most recent of these decisions[1] is useful in showing one of the boundaries of legal cruelty and also one of the possible remedies where a spouse suffers from refusal of complete sexual intercourse.

A husband, almost from the outset of the married life, performed partial intercourse by coitus interruptus in spite of the repeated protests of his wife and of his own knowledge that his conduct was increasingly injurious to her bodily and mental health. He abstained for varying periods, and after these had partial intercourse on occasions. On each of these occasions the wife genuinely hoped and believed that the intercourse would be complete and that she could bear a child. Each time she was frustrated, disappointed, and depressed, and her nervous system was disturbed, with the result that her health, both bodily and mental, suffered increasingly, for she keenly desired to raise a family and believed that her husband did also.

At last, losing hope of the marriage, she petitioned the court for nullity on the ground of the husband's sexual incompetence or wilful refusal to consummate the marriage, but the judge was not satisfied that the marriage had not been consummated. She accordingly petitioned for divorce on the ground of cruelty through a failure of the husband, consistent only with determination, properly to give her those sexual rights to which she was entitled, with the result that her health deteriorated and at one time at least was in a serious condition.

Mr. Justice Wallington did not doubt that the conduct of the husband, if continued, would have produced a serious and dangerous deterioration in her health, nor that he must have understood the wrong and injury that he was doing to his wife. The judge did not suppose that her whole well-being depended on sexual intercourse or that she thought that it did. Some women, he said, may be so constituted that their health is not affected by repeated partial intercourse, such as coitus interruptus, while other women enter into the marriage state hoping to fulfil one of its most important functions—the bearing of children. When such women are denied the normal means of child-bearing and their sexual functions are abused by frequent coitus interruptus, especially when it follows substantial periods of complete denial of intercourse, their health is likely to be affected. In his opinion the case before him fell into this class, and he granted the wife her decree. He mentioned, however, during his judgment that mere abstention by the husband from intercourse could not amount to cruelty or give the wife any remedy, even though it might injure her health.

There must, it appears, be aggravating circumstances of the kind related here, such as long periods of total abstention and callous indifference to the harm that was being done. Where such circumstances are present, however, a spouse may have a remedy if the nullity remedy fails.

J. Hockey, H. R. Odlum.

*By proxy.

In Congregation on August 20 the honorary degree of D.Sc. was conferred on the following: Viscount Addison, K.G., M.D., F.R.C.S., Lord Privy Seal, Leader of the House of Lords, and Chairman of the Medical Research Council; Carl Ferdinand Cori, Professor of Biochemistry in the University of Washington School of Medicine; Sir Charles Robert Harington, Ph.D., F.R.S., Director of the National Institute for Medical Research; Kaj Linderström-Lang, Director of the Carlsberg Laboratory, Copenhagen; Arne Wilhelm Kaurin Tiselius, Professor of Biochemistry in the Royal University of Uppsala, Sweden; Jacques Tréfouël, Membre de l'Institut et de l'Académie Nationale de Médecine and Directeur de l'Institut Pasteur, Paris.

UNIVERSITY OF GLASGOW

The following candidates have been approved at the examination indicated:

D.P.H.—Muriel S. Alexander, J. R. H. Berrie, G. S. Carrick, Flora C. Cowan, N. R. Cowan, Agnes C. Davidson, Katharin I. Kerr, Ruth A. Keymer, D. Livingstone, Margaret J. Macarthur, D. MacInnes, Ann K. MacLennan, J. Maxton, Agnes W. O'Gorman, Martha G. Robson (née Kennedy), Betsy D. Scott, M. Silver, J. M. Wallace, Elizabeth M. Whiteside, Jessie E. Wilson, T. S. Wilson.

UNIVERSITY OF LONDON

Anthony Clegg Cunliffe, M.D., has been appointed to the University Readership in Bacteriology tenable at King's College Hospital Medical School, from October 1.

John Laurence Malcolm, M.B., Ch.B., has been appointed to the University Readership in Experimental Physiology tenable at St. Mary's Hospital Medical School, from October 1.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended August 20. [No. 33

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1949 (a)	(b)	(c)	(d)	(e)	1948 (Corresponding Week) (a)	(b)	(c)	(d)	(e)

Rate per 1,000 total births (including stillborn)			25[illegible]					30		

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Deaths from measles and scarlet fever for England and Wales, London (administrative county), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

‖ Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Q Fever in London

On July 11, 12, and 13 three members of the staff of the pathological department and one nurse at a London hospital became ill with what appeared to be atypical pneumonia. All recovered, but subsequent investigation has shown that all now have significantly high agglutinations against *Rickettsia burneti*. The rickettsia has also been recovered from one sample of blood. The usual incubation period (10–24 days) has now expired, and there is no evidence of further spread of the disease in the hospital. The source of infection is being investigated.

This is believed to be the first occasion on which *R. burneti* has been recovered in this country. Although Stoker has found suggestively high titres in a few individuals, there has heretofore been no unequivocal evidence of a source of infection here.

Q fever was first distinguished as a human disease in Queensland, Australia, in 1935, and was thought to be tick-borne. Later, in Chicago and Texas, outbreaks occurred in slaughterhouses and were attributed to the inhalation of tick faeces or some other rickettsial-contaminated material. During 1944–5 the disease was recognized in Greece and the North Apennines. It has also been reported from Switzerland, France, Germany, Turkey, Morocco, and Algeria. In the U.S.A. endemic foci have been identified in California. In some outbreaks ticks have not been involved, and the mechanism of spread remains uncertain.

Although the present episode may be no more than an isolated importation it calls for special vigilance. Early recognition of the disease and the correction of any environmental factor likely to facilitate spread may prevent the establishment of endemicity. It is therefore desirable that outbreaks of atypical pneumonia should be brought to the notice of medical officers of health, especially infection in persons handling meat and milk in slaughterhouses and dairies. Facilities for routine laboratory diagnosis are not available in hospital laboratories. Serological studies will be undertaken through the Virus Reference Laboratory at Colindale in selected instances. Not all strains of Q fever are antigenically identical.

Q fever is an acute febrile disease closely simulating virus pneumonia. It is not easily differentiated from influenza, primary atypical pneumonia, psittacosis, and other obscure fevers. The disease is characterized by sudden onset which can be dated, headaches (commonly frontal, behind the eyes), weakness, sweating and chills, and body aches. Pleuritic pain and cough often occur, and the sputum may be blood-stained, although expectoration is as a rule scanty. As in virus pneumonia, physical signs are relatively slight compared with the radiological findings, which are, generally speaking, indistinguishable from those of primary atypical pneumonia. The white count is normal or decreased, with a relative lymphocytosis. Fever is usually high and persists for from one to ten days or more; in most cases it is of from three to six days' duration. Anorexia may be pronounced at the onset, and the fever may be very debilitating.

Q fever is distinguished from the other rickettsial diseases (epidemic typhus, scrub typhus, Rocky Mountain spotted fever, rickettsialpox) by the rarity of cutaneous lesions. A fine vesicular eruption of short duration may occur in less than 10% of cases. In Q fever the Weil-Felix reaction is negative. (See also an annotation in our issue of June 12, 1948, p. 1145.)

Poliomyelitis

Notifications in England and Wales in the week ended August 27 were poliomyelitis 258 (273); polio-encephalitis 22 (22). Figures for the previous week are shown in parentheses.

The following counties reported multiple cases (poliomyelitis and polio-encephalitis together): London 34 (35), Berkshire 3 (11), Cheshire 8 (6), Cornwall 5 (8), Derby 2 (9), Devon 4 (9), Dorset 2 (1), Durham 3 (2), Essex 13 (10), Gloucester 15 (5), Hertford 6 (3), Kent 9 (6), Lancaster 33 (29), Lincolnshire, Lindsey 3 (3), Middlesex 17 (13), Northampton 4 (6) Northumberland 6 (7), Nottingham 7 (10), Somerset 7 (5), Southampton 16 (11), Stafford 4 (6), Suffolk East 2 (0), Suffolk West 2 (3), Surrey 5 (7), Sussex East 4 (2), Sussex West 2 (3), Warwick 7 (4), Wiltshire 3 (4), Yorkshire East Riding 3 (1), Yorkshire North Riding 4 (1), Yorkshire West Riding 33 (50), Monmouth 2 (2).

Of the 15 cases reported from Gloucestershire 14 were in Bristol C.B. For the first time in five weeks there has been a small fall in notifications. Thus the curve of incidence so far this year has been very similar to that in 1947 though at a much lower level. The figures of notifications for the corresponding week (Week 34) of 1947 were: poliomyelitis 626, polio-encephalitis 50.

Discussion of Table

In *England and Wales* infectious diseases were less prevalent during the week. There were decreases in the notifications of measles 1,106, whooping-cough 101, dysentery 27, and diphtheria 19. There was an increase of 37 in the notifications of acute poliomyelitis.

The largest falls in the notifications of measles were Durham 104, Lancashire 85, Kent 80, Northumberland 71, Norfolk 69, Glamorganshire 68, London 65, and Warwickshire 62. The largest variations in the returns for whooping-cough were decreases in Yorkshire West Riding 38 and Staffordshire 33, with an increase of 40 in Lancashire.

Notifications of diphtheria reached a new record low level and were 14 below the previous lowest return. The chief feature of the returns for diphtheria during the week was a decrease in notifications in London 6.

Of the 30 cases of paratyphoid fever 20 were notified in Lancashire (Liverpool C.B. 8). The largest return for dysentery was 10 in Lancashire (Liverpool C.B. 6). An outbreak of food poisoning occurred in Carmarthenshire, and 196 cases were notified in the urban and rural districts of Llanelly.

In *Scotland* there were increases in the notifications of dysentery 29 and scarlet fever 26. Of the 83 cases of dysentery 62 were notified in the city of Glasgow. In the western area there were 9 more notifications of diphtheria than in the preceding week. The rise in the incidence of scarlet fever was contributed by the western area.

In *Eire* increases were recorded in the notifications of whooping-cough 43 and measles 23. There was a decrease of 23 in the notifications of diarrhoea and enteritis. Outbreaks of whooping-cough were notified from Donegal, Donegal R.D. 27, and Dublin, Balrothery R.D. 14, and there was an outbreak of measles in Carlow, Carlow R.D. 18.

In *Northern Ireland* an increase of 14 in the notifications of whooping-cough was the only noteworthy change in the trends of infectious diseases.

Week Ending August 27

Notifications of infectious diseases in England and Wales during the week included: scarlet fever 718, whooping-cough 1,671, diphtheria 52, measles 1,778, acute pneumonia 222, cerebrospinal fever 18, acute poliomyelitis 258, acute polio-encephalitis 22, dysentery 90, paratyphoid fever 25, typhoid fever 10, food poisoning 171.

Medical News

Films on Haematology

The first two of a series of films on "Animated Haematology" were recently shown to an audience in London. The films were produced by the Armour Laboratories in Chicago, with the collaboration of the Department of Medicine of the University of Illinois. The first is entitled "The Haemopoietic Principle," and the second "Bone Marrow." They are 1,600-foot, 16-mm. silent colour films and are suitable for teaching purposes and for showing at medical meetings. They may be borrowed free of charge from Armour Laboratories Limited, 2, Lindsey Street, London, E.C.1.

Pharmaceutical Research Fellowships

The Pharmaceutical Society announces the award of two Fellowships of the value of £300 a year for two years. The Ransom Fellowship has been won by Mr. R. A. Webb, B.Pharm., B.Sc., who will do research work in organic chemistry at the University of London School of Pharmacy. Mr. B. K. Martin, B.Pharm., won the society's own scholarship and will undertake an investigation of the synthesis of pteridines and other related heterocyclic compounds at Nottingham University.

Wills

Dr. John Christopher Davies, of Shrewsbury, left £41,960. Mr. Arthur Hedley Clarence Visick, of Fulford, Yorks, left £13,589. Dr. Henry Colin Maclaren, of Carlisle, left £5,970. Dr. David Cyril Thomas, of Winterton, Norfolk, left £13,130. Dr. Frederick Barnes Elwood, of Belfast, left £33,524. Mr. Ernest Lewis Lilley, of Scraptoft, Leics, left £44,038, including £250 to the Charities Fund of the B.M.A.

COMING EVENTS

N.A.P.T. and Medical Officers of Health

A joint meeting of the National Association for the Prevention of Tuberculosis and the Society of Medical Officers of Health will take place in B.M.A. House on Thursday, September 15, at 2.30 p.m. The chairman will be Professor R. H. Parry, president of the Society of Medical Officers of Health and medical officer of health, City and County of Bristol. The object of the meeting is to exchange views and experience on social and aftercare arrangements by local health authorities under the National Health Service. The following speakers will lead the discussion: Sir Allen Daley, London County Council; Dr. G. W. H. Townsend, Buckinghamshire County Council; Dr. W. Alcock, Burton-upon-Trent; Dr. Neville Irvine (B.C.G. Vaccination); and Miss Anne Topley, Care Almoner, Surrey County Council.

Cerebral Palsy

Dr. Earl R. Carlson, medical director of the School of Corrective Motor Education, Long Island, New York, will address a meeting to be held under the auspices of the British Council for the Welfare of Spastics at the Royal Society of Medicine (West Hall), 1, Wimpole Street, London, W., on Wednesday, September 21, at 5 p.m. The American film, "A Day in the Life of a Cerebral Palsied Child," will be shown after the address.

King's College Hospital Medical School

Sir Hugh Cairns will deliver the inaugural address at the opening of the 1949–50 session of King's College Hospital Medical School on Friday, September 30, at 3 p.m., with Sir William Gilliatt in the chair.

No. 2 General Hospital

The third reunion dinner of No. 2 General Hospital will be held at Simpson's Restaurant, 100, Strand, London, W.C., on Saturday, October 8, at 6.30 for 7.15 p.m., with Colonel E. Scott in the chair. Tickets (14s. for officers and nursing officers; 12s. 6d. for other ranks) may be obtained from Mr. A. E. Porritt, C.B.E., F.R.C.S., 10, Upper Wimpole Street, London, W.1.

French Refresher Course

A refresher course in medicine and surgery—Les Entretiens de Bichat—will be held at the Bichat Hospital, Paris, on October 10–15. Further particulars may be obtained from L'Expansion Scientifique Française, 23, Rue du Cherche-Midi, Paris, 6e.

American Public Health Association

The 77th Annual Meeting of the American Public Health Association and meetings of related organizations will be held at the Hotels Statler and New Yorker, New York City, on October 24–28. Information may be obtained from Dr. Reginald M. Atwater, Executive Secretary, American Public Health Association, 1790, Broadway, New York City.

Alvarenga Prize and Lecture

On July 14 the College of Physicians of Philadelphia (19, South Twenty-second Street, Philadelphia, 3, U.S.A.) awarded the Alvarenga Prize for 1949 to Owen Harding Wangensteen, M.D., Ph.D., Professor of Surgery, University of Minnesota, for his important contributions to the aetiology and therapy of gastric and duodenal ulcer. Dr. Wangensteen will deliver the Alvarenga Lecture on this subject at the College of Physicians of Philadelphia on November 2. The Alvarenga Prize was established by the will of Pedro Francisco daCosta Alvarenga, of Lisbon, Portugal, an Associate Fellow of the College of Physicians, of Philadelphia, to be awarded annually by the College on the anniversary of the death of the testator, which took place on July 14, 1883.

SOCIETIES AND LECTURES

Tuesday

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At Anatomy Lecture Theatre, Edinburgh University, September 13, 4.30 p.m., "*The Metabolic Response to Injury*," by Dr. D. P. Cuthbertson.

Wednesday

INSTITUTE OF PSYCHIATRY (UNIVERSITY OF LONDON).—At Maudsley Hospital, Denmark Hill, London, S.E., September 14, 5 p.m., "*Neurological Organization for Motion*." Public Lecture by Professor Warren S. McCulloch (University of Illinois, Chicago). All interested are invited.

Thursday

INSTITUTE OF PSYCHIATRY (UNIVERSITY OF LONDON).—At Maudsley Hospital, Denmark Hill, London, S.E., September 15, 2.15 p.m., "*Emotion from the Physiological Viewpoint*," Public Lecture by Professor E. Gellhorn (University of Minnesota). All interested are invited.

ROYAL INSTITUTE OF PUBLIC HEALTH AND HYGIENE, 28, Portland Place, London, W.—September 15, 3 p.m., "*World Trends in the Teaching of Social Medicine and Public Health*," Bengué Memorial Award Lecture by Professor René Sand (University of Brussels).

APPOINTMENTS

Dr. D. J. M. Mackenzie, O.B.E., Director of Medical Services, Nyasaland Protectorate, has been appointed an Official Member of the Legislative Council of the Protectorate.

EAST ANGLIAN REGIONAL HOSPITAL BOARD.—*Consultant Psychiatrist, Fulbourn Mental Hospital*, R. L. Buttle, M.R.C.S., L.R.C.P., D.P.M. *Second Consultant Pathologist, Norfolk and Norwich Hospital*, A. L. M. Christie, M.Sc., Ph.D., M.B., B.S. *Consultant Chest Physician, Ipswich and East Suffolk Area*, C. J. Stewart, M.D., D.Obst.R.C.O.G.

RAFFERY, LILIAN, M.R.C.S., L.R.C.P., M.M.S.A., M.R.C.O.G., Honorary Visiting Gynaecologist, King George V Springfield Hospital for Tuberculosis, Durban, South Africa.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Eedy.—On August 22, 1949, at Mansfield Nursing Home, to Françoise (née Chanu), wife of Dr. B. N. Eedy, a daughter—Bernardine.

Heap.—On August 21, 1949, at "One Oak," Pickering, Yorks, to Berry, wife of Dr. K. I. Heap, a son.

DEATHS

Alderson.—On September 3, 1949, Wilfred Ernest Alderson, M.D., formerly of 56, Highbury, Newcastle-upon-Tyne, aged 76.

Berry.—On August 31, 1949, at 3, All Saints Road, Clifton, Bristol, Beatrice Catharine, the wife of Professor R. J. A. Berry, M.D., F.R.S.E., aged 71.

Critchley.—On August 31, 1949, Samuel Edward Critchley, M.B., Ch.B., of 532, Chorley Old Road, Bolton.

Dewar.—On September 1, 1949, at Heathfield House, Whitefield, near Manchester, James Dewar, M.B., B.Ch., of Bury.

Fuller.—On August 31, 1949, at 5, Regent's Court, Hanover Gate, London, N.W., Charles Arthur Fuller, V.R.D., M.B., late of Cawnpore, India, aged 80.

Fulton.—On August 30, 1949, at 57, Burnley Lane, Chadderton, Frederick Fulton, L.R.C.P.&S.Ed., L.R.F.P.S.Glas.

Hernaman-Johnson.—On September 3, 1949, at Rotherfield Road, Carshalton, Francis Hernaman-Johnson, M.D., F.F.R., aged 70.

Hincks.—On August 26, 1949, at Wells, Somerset, Arthur Cecil Hincks, *M.C.*, M.B., Ch.B.

Lindow.—On August 26, 1949, Eric Delafield Lindow, M.R.C.S., L.R.C.P., of 19, Beaufort Gardens, London, S.W., late Malayan Medical Service.

Morgan.—On September 1, 1949, at North Walsham, Norfolk, Edward Morgan, M.R.C.S., L.R.C.P., aged 69.

Peacey.—In April, 1949, Winifred Peacey, M.R.C.S. L.R.C.P., of Hayle, Cornwall.

Stewart.—On September 3, 1949, at Wilton Villa, Ashton Road, Denton, Manchester, William Stewart, M.D., M.Ch.

Wells.—On September 2, 1949, at Wilcott, Sanderstead, Surrey, Harry Vernon Wells, F.R.C.S., aged 49.

Any Questions ?

Osteochondritis Dissecans

Q.—*What are the aetiology, prognosis, and treatment of osteochondritis dissecans?*

A.—The cause of osteochondritis dissecans is not known with certainty. It is generally agreed that it results from local loss of blood supply to an area of bone, but the primary cause of this is debatable. It is often attributed to trauma, which may lead to thrombosis of an end artery supplying a segment of bone. This is a reasonable hypothesis, and it is supported by the observation that in the knee the area of osteochondritis usually lies on the infero-lateral aspect of the medial femoral condyle immediately opposite a prominent tibial spine; it is supposed that impingement of the condyle against the tibial spine is the primary factor. When osteochondritis occurs in other areas of the knee, or in other joints, there is often—though by no means always—a history of previous direct injury. The pathological course of osteochondritis dissecans in the knee may be summarized as follows. Initially there is an area of avascularity of bone, which is shown in the radiographs as an area of increased density. The overlying articular cartilage degenerates. After a variable period, usually many months, the avascular fragment of bone separates and forms a loose body, leaving a crater in the bone which becomes filled with fibrin and later with fibrocartilage.

When the diagnosis is made before the fragment has separated it is often wise to await spontaneous separation, heavy use of the joint being avoided in the meantime. But if the knee is opened the avascular fragment should be gouged out, leaving a clean vascular bed. In doing this it is sometimes difficult to define the line of demarcation between avascular and healthy bone. When operation is deferred until spontaneous separation has occurred all that is necessary is to remove the loose body or bodies. After operation, a few weeks' rest, with intensive quadriceps exercises, is advisable. The prognosis depends on the size of the avascular fragment and of the resulting cavity in the articular surface, and on the position of the lesion. When the cavity is small and situated away from the major weight-bearing area of the condyle—for example, at the lateral aspect of the lateral femoral condyle—the prognosis is good; but when the main weight-bearing surface of a joint is involved, and particularly if the lesion is large, there is a risk of the development of degenerative arthritis months or years later owing to the loss of normal articular cartilage over the area of the lesion.

Treatment of Burns

Q.—*What is the modern treatment of burns?*

A.—Experience during and since the war has shown that treatment should have these aims: (1) to relieve the pain which follows the accident, and avoid pain later; (2) to prevent the onset of "shock," and steer the patient through it if it develops, by carefully controlled fluid replacement; (3) to prevent and control infection throughout the period of recovery; (4) to ensure regeneration or replacement of skin as early as possible; (5) to avoid or diminish metabolic disturbances resulting from injury, fever, or anaemia; (6) to encourage normal functioning of the injured parts and of affected joints, etc., and to maintain the patient's morale throughout; (7) by secondary repair or "plastic" operations to correct any defect or deformity which remains or develops after healing is complete.

Amplifying these aims very briefly, the following recommendations are made: (1) For limb burns, if immediate pain is not severe, hold them under the cold tap; if pain is severe, give "omnopon" and scopolamine. Cover burn with a sterile (or freshly laundered) towel until dressing can be undertaken. The avoidance of later pain is almost entirely a question of preventing and controlling infection (see 3 below) and depends on patience and skill in carrying out the dressings. (2) For severe burns involving a large area, intravenous transfusion of plasma or serum should be started if possible within an hour of the

accident, or as soon thereafter as may be. The rate of flow and quantity of fluid to be given should be regulated by repeated haematocrit or haemoglobin estimations, and by the general condition of the patient (see Gibson and Brown, M.R.C. Memorandum No. 249, 1944). Transfusion can usually be discontinued after 24 to 30 hours. Plenty of fluid, but only by repeated sips, should also be given by mouth during the first few hours—sodium lactate 1.75% solution for choice. (3) Burned areas should be first cleaned carefully with "cetavlon" solution 1%. (An anaesthetic is very seldom required if omnopon and scopolamine have been given.) Penicillin cream, 400 units per gramme in a paste of lanette wax and water, is smeared on thickly, and plenty of dressing applied with firm pressure by crêpe bandages (these are essential). Burns of hand and forearm should be elevated above the level of the heart for the first three to five days to reduce effusion. (4) The first dressing should be left untouched (if comfortable and the initial fever has subsided) for from seven to 14 days. Subsequent dressings, if there is no manifest infection, should be applied at intervals of five to seven days. To burns infected with haemolytic streptococci penicillin cream should be applied at intervals of two days until the micro-organisms have disappeared. Whenever possible all dressings should be carried out in "clean" air—that is, in a room supplied with an abundant stream of filtered air—or, where this is not available, in a room with good window ventilation. Great care should be taken that perfect coverage of the burned areas is obtained and maintained. For superficial burns, avoid infection, and epithelial regeneration will need no encouragement. For burns involving "whole-skin" loss of limited extent, grafting may often be undertaken with great advantage on the day of the accident (or within three days), after the burned tissues have been excised. Grafting at later periods should not usually be undertaken when haemolytic streptococci are present. Flexures in particular should be grafted very early. (5) Patients with severe burns should be given an abundant high-protein, well-balanced diet after the first two or three days, with in addition a liberal allowance of ascorbic acid. Anaemia, if severe, may call for one or more blood transfusions. (6) Early physiotherapy and occupational therapy are of value; great gentleness and patience in applying dressings are essential throughout the whole course of treatment.

Incubation Period of Tuberculosis

Q.—*Is any information available about the length of the latent period between infection with the tubercle bacillus and clinical manifestations of the disease?*

A.—In most cases infection with the tubercle bacillus is not followed by clinical manifestations in the sense of recognizable symptoms. A positive tuberculin reaction is the only evidence that infection has occurred. Wallgren has made a special study of "the time-table of tuberculosis" (*Tubercle*, 1948, 29, 245). He found that the important initial manifestations of tuberculous infection in children included transient fever, raised erythrocyte sedimentation rate, erythema nodosum, and the development of tuberculin-sensitivity and of the primary complex. The exact time infection occurred is often difficult to determine, but his studies suggest that the incubation period is usually about five to six weeks, although in exceptional cases it may be as short as three or as long as eight weeks.

Testing Swimming-bath Water

Q.—*A recent article seems to suggest that the results obtained when testing swimming-bath water for residual chlorine with o-tolidine reagent may not be reliable enough, and that, even if the water shows a high chlorine reading, this chlorine is not necessarily all available for sterilization purposes. Is this correct? The bacteriological examination of water means a wait of three to four days. If the residual chlorine test can still be regarded as reliable, it has obvious advantages.*

A.—Monochloramine, dichloramine, and even nitrogen trichloride may be produced when chlorine is added to water containing ammonium, depending on the conditions. The *o*-tolidine reagent will react with all of these. It does not, in the ordinary test, differentiate clearly between these, and it is therefore true to say that the test does not give a determination of chlorine alone. Nevertheless, as the chloramines are also bactericidal, although slower in action than chlorine, the *o*-tolidine reagent is probably still the best to employ for the control of purity. It is, of course, necessary in the control of swimming-bath water to ensure that the test is used after the break-point has been passed. Much work has been done on modifications of the *o*-tolidine test, and it is probable that a method will soon be published which will determine the actual amounts of chlorine, chloramines, and nitrogen trichloride present in chlorinated water.

Hunner's Ulcer of Bladder

Q.—*What are the modern views on the treatment of Hunner's ulcer of the bladder? The condition is complicated by severe rheumatoid arthritis which contraindicates extensive operative procedures.*

A.—It is perhaps unnecessary to say that Hunner's ulcer of the bladder is one of the more intractable conditions with which the genito-urinary specialist has to deal. Many forms of treatment have been tried, but without avail. One recognized form of treatment is distension of the bladder. The patient is taken into hospital or nursing-home and the bladder distended with increasing amounts of fluid. A solution of silver nitrate is often used for this purpose, beginning with a strength of 1 in 8,000 and gradually increasing up to 1 in 1,000. The bladder is distended once daily, the distension and strength of solution being increased according to the toleration of the patient. However, the writer has had little success with this treatment and it has the disadvantage of being painful; the only cure he has obtained when the condition is well established has been by operative measures. The whole of the affected area was excised, and the result was complete cure. If the patient is in great distress, so that life has become a misery, it would be justifiable to operate.

Fröhlich's Syndrome

Q.—*When examining school-children between the ages of 10 and 14 years one occasionally comes across a very fat child—if male, with one or both testes undescended, or, if female, with delayed menstruation. This combination suggests some endocrine dysfunction. It would be interesting to learn if any of the endocrine glands are involved, and if any hormone treatment is available. The hormone therapy for undescended testicle does not reduce the obesity, neither does dietetic treatment. What investigations are needed in these cases and what treatment?*

A.—Adiposity with failure of sexual development and failure of growth is known as Fröhlich's syndrome, and in some classifications a failure of growth is not regarded as essential for the diagnosis. However, from the point of view of treatment, the obesity falls into the same category as idiopathic obesity, for which there is no direct hormone therapy, and for which, as has been frequently indicated in these columns (Aug. 21, 1948, p. 408; Oct. 30, 1948, p. 808; March 5, 1949, p. 421; July 16, 1949, p. 189), the conventional treatment is diet, diuretics, and appetite-reducers, such as amphetamine sulphate. *X*-ray examination of the pituitary fossa should be carried out, but is usually negative.

Price's Precipitation Reaction

Q.—*How does Price's precipitation test for syphilis compare with other precipitation tests and the Wassermann reaction as regards specificity and sensitiveness? What is the technique of this reaction?*

A.—According to its originator, Price's precipitation reaction is less sensitive than the Kahn test, but considerably more specific. It is less sensitive than the Wassermann reaction, but of about the same degree of specificity. The technique of the test is described by Price, I. N. Orpwood (*J. clin Path.*, 1948, 1, 91), and his experience in the use of the test is given in *Brit. J. vener. Dis.* (1949, 25, 67).

Esbach's Test

Q.—*Esbach's test can be very misleading, and it is surprising that textbooks do not mention this. The only reference I have found is on page 640 of Martindale's Extra Pharmacopoeia, 1943 ed., vol. 2. By employing a simple method I have been able to arrive at a more correct quantitative reading of albumin content, and would be glad of an opinion about the correctness of the method and the accuracy of the deductions. Finding a heavy precipitate in Esbach's albuminimeter which I could not reconcile with clinical findings, I turned out the column of fluid and precipitate into a test-tube and boiled it for a few minutes, when much of the precipitate went into solution. After cooling, the contents were transferred into Esbach's tube and allowed to stand for another 24 hours, at the end of which the reading, which had originally been 4 g. per litre, was only 0.5 g. As boiling brings down albumin, it must be concluded that the original high reading was accounted for by substances other than albumin. What are the other substances which precipitate in Esbach's reagent?*

A.—On account of its simplicity, Esbach's test is often used by clinicians, but it gives only a rough measure of protein content and is too inaccurate for use in the laboratory. In this test it is assumed that a given weight of protein precipitated from urine always occupies the same volume regardless of variations in the composition and density of the urine. This cannot be true, because the state of aggregation of colloidal precipitates of proteins is known to vary with physical conditions. Furthermore, the test has not been properly standardized. For instance, there are variations in the composition of the recommended precipitating solution, and the temperature conditions are not specified. The method given in Martindale's *Extra Pharmacopoeia*, which involves heating to 180° F. (82.2° C.) and centrifuging for a few minutes, might well yield different results from the more usual routine. Substances other than protein which may be precipitated are uric acid and urates, and the excretion product of "uroselectan"; other substances mentioned as interfering with the result are creatinine, resin, unspecified acids, methylene blue, and alkaloids.

To explain the decrease after boiling reported in the question would require a careful chemical examination of the particular specimen tested, but it is possible that the boiling may have converted some protein to metaprotein, or have changed it physically so that it occupied less volume. Alternatively, as the question suggests, boiling may have removed some interfering substance. The inquirer's variation of the test—namely, boiling the mixture—has probably little to recommend it. If a satisfactory determination of protein is required, then a recognized chemical estimation should be used—for example, a Kjeldahl or biuret determination. It is unfortunate that several textbooks describe Esbach's test without giving any warning of its inaccuracy, but Harrison makes some pertinent comments on the test (*Chemical Methods in Clinical Medicine*, 3rd ed., 1947, Churchill, pp. 44 and 52).

Sex Hormones and the Hair

Q.—*Three women in their middle fifties have complained recently of a lack of lustre in their hair. In each case the patient dated the condition from a large intake of stilboestrol. The hair was lifeless and in texture resembled cat's fur. Stilboestrol has been withdrawn. Would the male hormone in suitable doses help to restore the condition of the hair?*

A.—It is very unlikely that stilboestrol has adversely affected the scalp hair, as in Simmonds's disease it improves the texture and colour of the hair (S. L. Simpson, *Proc. R. Soc. Med.*, 1948, 41, 192, and Section of Endocrinology, p. 6). It is theoretically possible that the dosage was so large as to produce degranulation of the anterior pituitary cells and a type of hypopituitarism. Testosterone, or methyl testosterone, improves the lustre and colour of the hair in Simmonds's disease (*ibid.*), and might therefore prove helpful in the cases referred to. In very large doses, however, it causes some loss of scalp hair in the temporo-frontal regions, as in virilism; it also makes the hair somewhat coarse in texture.

Delayed Speech

Q.—*What would cause backwardness in speech in a girl aged 4, who seems healthy and intelligent but is still unable to form any sentence of more than two or three words, which are unintelligible to a stranger? She has a brother aged 6 who has always spoken remarkably well for his age, and she meets other children frequently. Is there any treatment?*

A.—There are many causes of retardation of speech in normal children, and some very intelligent children have been known to delay talking until after 4 or 5 years of age and then to speak fluently. It is possible that in this case a cause for the delayed speech may be the unusual ability of the elder brother, who might unwittingly deter his younger sister from talking, either by acting as interpreter so that she need not voice her own demands or by demonstrating too high a standard in a way unintelligible to her. It can be very difficult for a younger child to understand an older one talking rapidly. And then much depends on the way parents and other adults speak: this should be clearly and slowly, encouraging response but without demanding it. There is, of course, a serious possibility of speech being delayed by some type of deafness, and this could be ascertained by tests such as those devised for young children by Dr. and Mrs. Ewing, of Manchester.

NOTES AND COMMENTS

Delirium Tremens.—Dr. R. M. YOUNG (Macclesfield) writes: I have been shocked to read both the answer about delirium tremens and the note from Dr. A. E. Carver ("Any Questions?" July 23, p. 242, and August 27, p. 496). Surely it has been accepted for many years that delirium tremens is a manifestation of vitamin-B$_1$ deficiency, due to the anorexia of the alcoholic in combination with failure of absorption due to the chronic poisoning of the alimentary canal. Be that as it may, your correspondents will find that delirium tremens responds in a matter of hours, almost minutes, to adequate vitamin-B therapy parenterally. A proprietary preparation containing suitable amounts of the whole group exists, or 200 mg. of nicotinic acid can be given intravenously. Aneurin hydrochloride (50 mg.) is given as well. The choice of sedative scarcely matters, but 2–3 oz. (56–84 ml.) of paraldehyde by mouth, suitably diluted, is excellent. A nasal tube may be used if the patient is not able to co-operate; and since, if this is so, exhaustion and dehydration are likely to be severe the opportunity should be taken to give a pint of milk or water with such added nourishment as is at hand—glucose, raw eggs, hydrolysed protein preparations. The patient will wake up clear, rational, and with a ravenous appetite which will complete the "cure." With any other form of treatment the death rate is high. In milder cases the vitamins seem to prevent the pangs of sudden withdrawal and the craving for a "hair of the dog" first thing in the morning. In these and in cases of delirium tremens after the crisis is past the vitamins can be given in tablet form in the following doses (t.d.s.): tab. acid. nicotin., 100 mg.; tab. aneurin hydrochlor., 10 mg.; tab. riboflavin, 3 mg. The patient should be warned to expect the hot flush which follows adequate dosage with nicotinic acid.

Correction.—Dr. ALAN J. HIRD (Glasgow) writes: I am sorry to say that an error has arisen in my article on Mikulicz's syndrome in the *Journal* of August 20. This is on p. 417, column 1, line 26. The term "deep *x*-ray therapy" (200 Kv) should apply only to the general or body irradiation. The local irradiation to salivary and lacrimal glands was with low-voltage therapy (85 Kv) so as to minimize the possibility of undesirable effects upon the eyes or secreting tissues.

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL
LONDON SATURDAY SEPTEMBER 10 1949

THE SECRETARY REPORTS

GENERAL PRACTITIONER REMUNERATION

It will be recalled that the case for increasing the remuneration of general practitioners in the National Health Service was put to the Ministry of Health in early March, and a deputation from the General Medical Services Committee subsequently visited the Ministry. The reply the Ministry gave was that it was not prepared to discuss the case until complete information about the moneys actually received by general practitioners from the Service was available, and that the collection of this information had begun.

At long last the report on this investigation has been completed, and we received the document on August 18. It is a mass of statistics, containing some 244 pages, for the most part detailed tables. The General Medical Services Committee held a special meeting on August 31 to consider this document. It had expected to be in a position to communicate the substance of the document and its views on it to local medical committees immediately, but the longer the committee scrutinized the document, with the help of an eminent actuary, the more did it become convinced that there were important discrepancies which invalidated the conclusions which the Ministry appeared to draw from the document.

Accordingly, the Committee prepared a list of its criticisms and asked the Ministry to receive a deputation at the earliest possible date, with a view to a revision of the document in the light of the criticisms.

Owing to the absence of important officials concerned the Ministry is unable to receive a deputation before September 23. The Committee, which of course is not responsible for this further delay, will make a statement at the earliest possible moment after its discussion with the Ministry.

Annual Report of the Medical Practices Committee

The first annual report of the Medical Practices Committee has just been published and is well worth reading. The text of the report is reproduced in this issue of the *Supplement*, and it may be useful to draw attention to certain significant points. For example, the Committee states that it has never opposed a desire that a replacement should be allowed for a doctor leaving any practice, whether the desire was expressed by an executive council, a practitioner himself, his partners, or occasionally by outside bodies. The report reveals that partnerships are multiplying and that many assistants have become partners of, or successors to, their principals. The Committee emphasizes the view that preliminary apprenticeship as an assistant is still the best method of entry into general practice.

The Committee has never refused admission to the medical list for the purpose of starting a practice against the advice of the executive council concerned or the local medical committee. In carrying out its statutory duty, however, the Committee has been compelled to admit applicants to the medical list against the advice of some executive councils that they be refused, particularly in connexion with applications made by doctors who were already on the medical list for the area in which they resided and who applied for inclusion in the medical list of an adjoining area.

The power to transfer patients from a doctor whose services are withdrawn to another practitioner is vested not in the Medical Practices Committee but in executive councils. If the transfer is to a doctor already on their list it can be effected by the executive council without the permission of the Medical Practices Committee. Usually the transfer is made in favour of the particular applicant for a vacancy who has been selected by the Medical Practices Committee. The effect of this is that an unsuccessful applicant who appeals to the Minister and succeeds in his appeal finds that his admission to the list may not result in succeeding to the patients, which was his desire and the reason for his application and appeal. Moreover, if an unsuccessful applicant's name is already on an executive council's medical list he has no appeal against the selection of another practitioner to succeed to a practice in that area.

The Committee has completed its survey of the number of general practitioners practising in the various parts of England and Wales, and has published schedules of "open," "closed," and "doubtful" areas (*Supplement*, August 6, p. 70).

The Committee has attached great weight to the undertaking given by the Minister to the profession in April, 1948, that "every doctor will be free to practise where he chooses, unless it is one of the areas where the Medical Practices Committee decide no more doctors are needed in the Service. In all cases except the latter, 'consent' will be automatic."

In areas which have not been declared "closed" or "doubtful," it follows therefore that the consent of the Committee to admit a doctor to the medical list will be granted automatically. The question may be asked, in connexion with the filling of a vacancy, How can the promise of automatic consent be reconciled with the statutory duty of the Committee, in cases where the number of applicants exceeds the number required, to select the persons whose applications are to be granted and to refuse the others?

In its report the Committee clarifies this apparent anomaly. It states:

> "The unsuccessful candidates are informed of their rejection and of their right of appeal if they are not already on the medical list of the executive council concerned, and in all cases where the area is not 'closed' or 'doubtful' are advised that the Committee's decision does not prejudice any application that may be made to come on the list otherwise than in respect of this particular practice. Should intimation be received from any such candidate that admission to the list is desired in these circumstances it is granted forthwith. This procedure may carry all the advantages of a successful appeal to the Minister against the decision of the Committee and is indeed preferable in many cases because admission to the list would be considerably expedited as compared with the time which would elapse before admission to the list on successful appeal."

Even the "closure" of an area, the Committee points out, should convey no more than that the Committee is unlikely to agree to an increase in the number of practitioners practising in the district in question and might agree with an executive council to refuse to allow replacement of what might be regarded as redundant practitioners resigning from the list.

This does not mean, however, that a retiring practitioner could not be replaced. Indeed, it is asserted in the report that, in every case where an executive council in agreement with the local medical committee considered replacement desirable, the Medical Practices Committee would agree. Nor does it mean that under no other circumstances would the Committee admit a practitioner to the list; personal factors advanced by the applicant or, in his favour, by the executive council, the local medical committee, or other interested parties might be considered of sufficient weight to cause the application to be granted.

MEDICAL PRACTICES COMMITTEE

FIRST REPORT

To the Rt. Hon. Aneurin Bevan, M.P., Minister of Health.

The Medical Practices Committee for England and Wales established under the National Health Service Act, 1946, in July, 1948, is concluding its first year's work. In particular it has just completed a comprehensive survey of the distribution of practitioners providing general medical services under Part IV of the Act. During the year the Committee has been closely in touch with the Ministry of Health upon many matters, and the Department has been made fully aware of the detailed decisions of the Committee by receipt of the full minutes of the meeting. The Committee is not enjoined by statute to furnish a general report of its observations and activities; nevertheless, the Committee decided that a review of its work would be of value to itself, and that some general remarks thereon might be of value to the Minister. Accordingly we have the honour to present briefly such a report.

General Tendencies

The Minister is aware that it was hoped that most of the general practitioners in the country would join the Service. A figure of under 18,000 general practitioners for the whole country, including Scotland, was anticipated, and certain considerations important to the profession depended upon this figure being reached. The number of general practitioners in the Service by July 5, 1948, was approximately, we understand, 20,000. There had in fact been about 2,000 new entrants into general practice in the few months immediately prior to the appointed day. This increase was largely due to the impact of the Act and uncertainty in the minds of the profession. Some genuine concern at the possible activities of this Committee was, we believe, a strong factor in the decision on the part of practitioners to attempt to settle a place of practice before the Act came into force. A natural reaction to this has been manifest during the past year. Some of these new entrants into practice have done well and have succeeded in establishing themselves. Not all were wise in their choice of location. Some of those who chose the more desirable residential regions have been obliged to contemplate and to seek transference to other areas or other employment. The same effect of economic circumstances, though to a lesser degree, has been noted with established practitioners. Since the appointed day in areas desirable from a residential point of view many retiring practitioners have not been replaced; the three-man practice may have become a two-man practice, and the single practice dispersed. Many of these practitioners have re-entered practice in other parts of the country and others are awaiting the opportunity to do so. This Committee has never opposed a desire that a replacement should be allowed for a doctor leaving any practice, whether the desire was expressed by an executive council, a practitioner himself, his partners, or occasionally on representations by outside bodies.

At an early stage it became apparent that a large number of doctors who were not in practice wished to join the Service after the appointed day and to know the districts in which they could start a practice. To meet this situation the Committee circularized all executive councils on July 30, 1948, and asked to be informed of any districts in their area which were manifestly under-doctored. The replies received indicated that executive councils generally considered the service in their areas adequate and in few instances only suggested that further doctors were required. Subsequent inquirers were informed of these places.

Apart from this it was not possible before the receipt of the full reports from executive councils to tell intending applicants where further doctors were required. In order, therefore, that such applicants should have a firm opinion as to whether or not any application would be granted before undertaking a financial liability for the acquisition of property, arrangements were made with executive councils for provisional applications to be considered by them for transmission to this Committee. The applicants, in these cases, were informed that their applications would be granted if they could secure surgery accommodation in the district within a period of three months and that this period might be extended if on its expiry they satisfied the Committee they were still actively seeking accommodation.

Partnerships are multiplying and new practices are being started. Difficulty in obtaining suitable premises from which to conduct a practice alone prevents this process from being greatly accelerated. Many assistants have become partners of, or successors to, their principals, and the Committee considers that preliminary apprenticeship as an assistant is still the best method of entry into general practice.

What it is desired to emphasize is that the impact of the Act itself and the economic circumstances of medical practice which flow from it are already exercising an effect upon the distribution of general practitioners in England and Wales. This Committee is in a favourable position to assess this movement, which is in the direction desired and is being achieved without coercion by any statutory body.

Survey of the Country

Probably the most important function of the Committee is the admission of doctors to the list of executive councils under Section 34 of the Act. It early became apparent that the ideas of, and the advice tendered by, some executive councils varied far beyond the limits of what might reasonably be expected as variations in local conditions and customs and indicated their misunderstanding of the Committee's limited powers. The Committee accordingly issued a circular on the subject to executive councils (*Supplement*, December 11, 1948, p. 213). While due weight is always given to the views of an executive council (acting in consultation with the local medical committee), had we acted upon this advice in all cases "the numbers of medical practitioners undertaking to provide general medical services" would have been declared "adequate" in many more areas of the country and such areas closed to new entrants. In order to maintain for the public the greatest possible freedom of choice of doctor and to preserve for the practitioners the right to practise in any part of the country (save in the exceptional circumstances contemplated by Parliament in Section 34/3) the Committee has required of executive councils the most cogent argument and the fullest information that the number of practitioners was indeed adequate and likely to remain so for some time before exercising its powers under the Section to refuse any application.

This method of dealing with the problem, while necessary at the start of the Committee's work, could not be considered satisfactory as a permanent procedure. It was manifestly desirable for the public, the doctors, the Ministry, executive councils, and the Committee itself that the position should be more precisely defined. The Committee could not be in a position to do this until executive councils had rendered full reports on their respective areas. These first reports, which by regulation cover the position up to December 31, 1948, have now been received and studied by the Committee and the position clarified.

As a result of preliminary consideration which the Committee had given to the matter it became evident that most of the executive councils' areas in England and Wales would be regarded as completely open for any doctor to start a practice wherever he chose and that admission to the executive councils' list would follow automatically upon application to be so admitted without any restriction whatsoever.

In considering the reports furnished by executive councils, the Committee noted that in industrial areas the doctors had larger lists than in the residential or urban areas. It may be necessary at some later stage to consider whether or not some special action such as inducement payments or assistance in obtaining premises should be taken to encourage more practitioners to start practice in what may be regarded as the less attractive industrial areas. It became equally evident that in certain executive council areas, or parts of them, it would be a waste of medical man-power to allow additions to the medical list of the executive council concerned for the purpose of practising in those parts and that such areas should be closed.

In a few areas the position was less evident, and the Committee felt a decision might well depend upon day-to-day circumstances and that these areas should be designated as "doubtful." The applicants to practise therein would be warned that the chance of establishing themselves in practice was likely to be difficult and that permission to make the attempt would not necessarily follow upon such application; the Committee would act upon information before it at the time of the application and might then declare the area closed. The types of area mentioned above have been labelled for convenience by the Committee as "A" areas (completely open), "B" areas (doubtful), "C" areas (closed). For its own information the Committee has arranged various subdivisions of these categories; one only such subdivision is likely to be of interest to the Minister, the executive councils, and to the profession—namely A1, which index expresses broadly the opinion of the Committee that such areas require additional general practitioners as a matter of priority. Publication of the names of such areas should encourage practitioners to go where their services are most needed and where the chance of successfully establishing themselves is greatest.

It became obvious that there was considerable misunderstanding about the implications to be drawn when the Committee closed any area. Accordingly a memorandum was prepared giving the Committee's own views on this point, with the idea of removing such misunderstanding (*Supplement*, December 11, 1948, p. 213). The practical effect of this is that, even in a closed area, the Committee would give special consideration to any representation made by either the executive council or the local medical committee, as they are at present constituted, that an application should be allowed. The Committee further considered that special representations of a personal nature made by or on behalf of an applicant might cause the Committee to admit to the list in a closed area. Such circumstances are likely to be exceptional, but the trend of the Committee's policy emphasizes its anxiety to preserve for the public and the profession the maximum possible freedom compatible with the efficiency of the Service.

After consideration of the detailed reports issued by executive councils the Committee made known to them its proposals in respect of their areas and invited the observations of the Council about all except those parts designated "open." Only in a limited number of cases has comment upon such proposals been received.

Having regard to all such advice received, the Committee has now published its decisions classifying the whole of England and Wales (*Supplement*, August 6, p. 70, and August 20, p. 93). The list of closed areas therein cancels and replaces any list or decision to close any area or part of an area which was published or arrived at prior to consideration being possible of the country as a whole. The classifications must constantly remain under review in the light of changing circumstances.

The Committee owes a great deal to the clerks and staffs of executive councils for the manner in which in a great number of cases they have promptly supplied the information desired and in many cases presented reports of the utmost value and beyond the scope requested by the Committee as a minimum of information the report should contain. From the experience so far gained the Committee is in a better position to specify the kind of information it requires for the purpose of future reviews.

One executive council has failed to furnish a report on its area.

Admissions to Medical List

(*a*) *Applications to Start Practices.*—The admission of applicants to the medical list of an executive council after the appointed day is a function of the Committee alone, subject to the right of appeal against the decision of the Committee in the event of a refusal. The Committee has never refused admission to the list for the purpose of starting a practice against the advice of the executive council concerned or the local medical committee. The Committee in carrying out its statutory duty has, however, been compelled to admit applicants to the medical list against the advice of some executive councils that they be refused. This has been particularly noticeable in connexion with applications made by doctors who are already on the medical list for the area in which they reside and who apply for inclusion in the medical list of an adjoining area for the purpose of treating patients resident in that area. Generally the Committee considers that such applications should be granted, but it of course remains the function of the executive council concerned after his admission to its list to satisfy itself that the practitioner's arrangements for attending the patients he accepts are adequate.

The number of applicants for admission to the list as principals since the appointed day is set out in an appendix which also shows the class of application—i.e., resident area or "fringe" area. The small proportion of refusals by the Committee of applications will be noted.

(*b*) *Assistants.*—Some difficulty has arisen in connexion with the admission of assistants to the medical list, and there is a body of responsible opinion that considers assistants should not be so admitted. The Committee has had discussions with officers of your Department, the Executive Councils Association, and representatives of the profession on this question, and it is hoped that an amendment of the Regulations may be made in the near future to clarify the position. The Committee wishes to re-emphasize that it considers that preliminary apprenticeship as an assistant is still the best method of entry into general practice.

(*c*) *Applications for Vacancies.*—A different problem faces the Committee when the question of selecting a practitioner to succeed to an established practice arises. In neither the Act nor the Regulations is any differentiation made between the function of the Committee selecting a candidate for a particular practice and admission to the list for the purpose of starting a practice in an area, and indeed the former case is not specifically dealt with at all.

Executive councils have the power to transfer patients from a doctor whose services are withdrawn to another practitioner. If the transfer is to a doctor already on their list it can be effected without the permission of this Committee. Usually the transfer is made in favour of the particular applicant for a vacancy who has been selected by ourselves. The effect of this is that an unsuccessful applicant who appeals to the Minister and succeeds in his appeal finds that his admission to the list may not result in succeeding to the patients which was his desire and the reason for his application and appeal. Further, if an unsuccessful applicant's name is already on the council's medical list he has no appeal against the selection of another practitioner to succeed to a practice.

The procedure of selection by us where there is a number of applicants for a vacancy necessarily varies according to the manner in which the executive council itself acts. In most cases now the executive council prepares a short list of the most suitable candidates and after interviewing these recommends the candidate for selection. Except where it might appear that the executive council has overlooked some salient point in an application which might prove on appeal to be a decisive factor or has failed to give what the Committee considers to be proper consideration to the applications as a whole, the Medical Practices Committee accepts the recommended candidate. In other cases an executive council may recommend a short list of the applicants whom it suggests we should interview or such may be prepared by the Committee itself. In any event all applications are required to be considered by the Committee, and on occasion we have added to the council's short list.

The total number of applicants called for interview by the Committee to date is 191. We have been impressed by the keenness of most of the applicants and have noted that generally the competition is greater for practices in the southern part of the country. The applications are not all from practitioners wishing to enter general practice as principals for the first time, but include doctors already in the Service or other branches of medicine who wish to make a change for various reasons. Having made its selection, the Committee regards the other applications in respect of the particular vacancy only and refuses them. The unsuccessful candidates are informed of their rejection and of their right of appeal if they are not already on the medical list of the executive council concerned, and in all cases where the area is not "closed" or "doubtful" are advised that the Committee's decision does not prejudice

any application that may be made to come on the list otherwise than in respect of this particular practice. Should intimation be received from any such candidate that admission to the list is desired in these circumstances it is granted forthwith. This procedure may carry all the advantages of a successful appeal to the Minister against the decision of the Committee, and is indeed preferable in many cases because admission to the list would be considerably expedited as compared with the time which would elapse before admission to the list on successful appeal.

After consultation with your officers, the Committee has agreed on a revised procedure for dealing with applications for vacancies, and it is hoped that this procedure will be agreed by representatives of the medical profession and put into operation.

The Committee in any selection it makes and in advice it tenders to and receives from executive councils is in particular mindful of any desires expressed by a practitioner to enter into partnership with others already on the list and who wish to have the applicant as a partner in accordance with Section 34 (9) of the Act. Especially is the Committee anxious that nothing should disturb existing arrangements made between partners in established practices.

Appeals

In several cases the selection of an applicant by the Committee has been the subject of appeal to the Minister. Some of these appeals have been decided after oral hearing and others on written representation only.

The Committee, like any other body attempting to maintain a properly judicial attitude in arriving at its decisions, is naturally anxious that such should not be upset on appeal. Nevertheless where this has been the case the Committee readily acknowledges that the machinery of appointment may well have failed to function to the best advantage. Unfortunately the delay in arriving at a decision on appeals may result in great difficulties and even hardships. If any way of arriving at decisions more speedily can properly be devised it will be to the advantage of all concerned.

124 vacancies have been advertised by executive councils and dealt with by the Committee. A total of 2,998 applications were received in respect of them. This involved some 2,800 refusals by the Committee, and of this number 35 doctors appealed to you against our decision.

Results of appeals are awaited in seven cases, but the Committee is glad to be able to record that of the cases decided its decision has been upheld in all but two. The winning of one of these was indeed a pyrrhic victory.

Certificates

Applications for certificates under Section 35 (9) are regularly received for consideration by the Committee. Many of these deal with the sale of property, and in such cases the assistance of the district valuer is sought through the chief valuer's department. This has proved most valuable to the Committee. In cases where there has been a difference of opinion as to the proper value to be attached to property, a direct approach by the district valuer to the interested parties has seldom failed to result in agreement.

Other certificates in respect of partnership deeds, deeds of variation, etc., are also regularly applied for and the advice of the Committee sought as to the terms of such deeds. In the majority of cases the Committee is able to grant the certificate forthwith. In some instances approach to the parties concerned or their representatives results in such modification as to enable the Committee to certify. The final refusal of certificates has been infrequent.

Applications for certificates under Section 37 of the Act were a major problem in 1948, but are now almost all dealt with, only a few outstanding cases remaining. The Committee has been able to grant the required certificate in most instances; occasionally, when refusal has been necessary, it has felt the greatest regret that this was so. Such refusal would have been more frequent but for the advice of the legal members of the Committee and of the Department. As a result the Committee has been able to issue certificates which it might otherwise have felt compelled to refuse though at the same time believing that injustice would have been done by such refusal.

Inducement Payments

The Department has consulted this Committee in connexion with 112 applications which have been made for inducement payments, and with the exception of eight of these cases the Committee was in agreement with the provisional payments proposed by the Ministry. Of the eight applications where we suggested a higher figure than that proposed, the Ministry accepted our recommendations in four cases.

The Committee is fully conscious of the details of organization, so well accomplished by our secretary, Mr. Bishop, and his staff, and desires to place this on record. Its relationship with the Department has been cordial and the help given to it by the Ministry greatly appreciated.

Liaison between the executive councils through their national association and the representative professional association and ourselves has also been cordial, and has resulted in many of the inevitable differences of opinion and difficulties which were bound to be experienced and have arisen from time to time being satisfactorily met. We believe that the mutual confidence which has been established in many quarters will result more nearly in unanimity.

APPENDIX

Schedule of Appointments to and Withdrawals from Medical Lists, made by or reported to the Committee

(i) *PRINCIPALS—Resident Areas*

(*a*) Total on medical lists at July 5, 1948		17,438
(*b*) Admissions since July 5, 1948		1,063
(*c*) Withdrawals since July 5, 1948	Deaths 180; Resignations 781	961
(*d*) Refusals (other than for vacancies) since July 5, 1948		14
(*e*) Admission as partners since July 5, 1948 (number included in (i) (*b*) above)		276

(ii) *PRINCIPALS—Fringe Areas*

(*a*) Total on medical lists at July 5, 1948		8,872
(*b*) Admissions since July 5, 1948		876
(*c*) Withdrawals since July 5, 1948	Deaths 13; Resignations 93	106
(*d*) Refusals		3

Included in (i) above for resident areas, and in addition these doctors' names may appear on several executive councils' lists for "Fringe" purposes.

(iii) *PRINCIPALS—Limited Lists*

(*a*) Total on medical lists at July 5, 1948	574
(*b*) Admissions since July 5, 1948	315
(*c*) Withdrawals since July 5, 1948 (Resignations)	47
(*d*) Refusals	Nil

(iv) *PRINCIPALS—Maternity List only*

(*a*) Total on medical list at July 5, 1948	36
(*b*) Admissions since July 5, 1948	3
(*c*) Withdrawals since July 5, 1948	Nil
(*d*) Refusals	Nil

(v) *ASSISTANTS*

(*a*) Number of assistants to resident doctors at July 5, 1948	562
(*b*) Applications granted since July 5, 1948	670

Certificates

	Granted	*Refused*
Section 35 (9)		
Property	57	4
Deed of partnerships	99	4
Section 37	183	25

ANNUAL REPORTS AND MEETINGS

According to a recent circular, a number of boards and committees have raised with the Minister of Health the question of annual meetings and the publication of annual reports by boards of governors and management committees.

The Minister welcomes the holding of annual meetings open to the public, and the issue of annual reports, as a means of stimulating local interest. The reasonable cost of these activities may be charged to the Exchequer account.

The question has been raised whether the accounts of boards and committees, whether audited or not, should form part of the annual report. In the view of the Minister it would be improper for the accounts of individual boards and committees to be published locally until the annual summary accounts have been presented to Parliament by the Comptroller and Auditor-General, as required by Section 55 (4) of the National Health Service Act. These accounts cannot, at the very earliest, be presented before December of each year, and as boards and committees will no doubt wish to issue any annual reports in the spring or early summer it would be possible only to publish accounts relating to the year previous to that covered by the report. Although there would be no objection to such a course the Minister feels that there would be little local interest in accounts issued at such a late date, and it will no doubt be thought preferable that reports should be issued without making any reference to the finances of the board or committee.

It is understood that some boards and committees desire to make their reports available to members of the general public, and where this is the case copies should be sold at cost price. Annual reports should, in the Minister's view, cover the activities of the board or committee as a whole, and separate reports should not normally be produced for individual hospitals in a group.

PROVISION OF DENTURES

A circular recently addressed to dentists may also be of interest to doctors. Apparently some dentists seem to be under a misapprehension about the stage—following extractions—at which a denture may be provided to a patient receiving general dental services. There is no requirement in the regulations governing the provision of general dental services, as there was under the old dental benefit scheme, that dentures shall not be fitted until absorption is sufficiently complete for "permanent" dentures (as distinct from "immediate" dentures) to be supplied. Subject to the general requirement that all treatment must be proper and necessary treatment, it is open to the dentist to provide dentures as soon as he considers that the patient's mouth is in a satisfactory condition to receive them.

No matter at what period after extraction dentures are provided during the currency of the dental estimate form, it should be clearly understood that no fee is chargeable to the patient for their provision. Initial loss of fit due to absorption may occur in some cases and can usually be made good by relining. If in the course of time the degree of absorption is such that function cannot be maintained by relining, a new denture will become necessary. The relining or, more rarely, the replacement can also be provided under the general dental services, subject to the approval of the Dental Estimates Board in the usual way.

TREATMENT EQUIPMENT

Another recent circular from the Ministry of Health states that there are certain types of expensive equipment—for example, oxygen tents, breathing machines, power-driven and gas-operated atomizers or inhalers—which may be needed at short notice for the treatment of patients in hospital or at home. It is important that equipment of this kind should be instantly available, but it would be wasteful and inefficient for each hospital to hold and maintain it. Regional hospital boards and boards of governors are therefore asked to concert arrangements by which certain larger hospitals would be prepared on request to lend equipment of this kind to other hospitals in their areas and, on the recommendation of a specialist, to patients for treatment in their homes. These arrangements should ensure that the equipment is properly maintained so that it would be ready for immediate use, and that adequate provision is made for its prompt delivery and collection.

Although arrangements can be made for the hire of some types of equipment, this is not recommended, as it will generally be found cheaper to purchase outright. These special types of equipment should be lent for the treatment of patients at home only on the recommendation of a hospital specialist after examination at an out-patient clinic or at a domiciliary visit. The patient or his representative should be asked to sign a statement that he understands the equipment remains the property of the hospital and that he will be liable to pay the cost of repair or replacement if it is not returned in good condition. Regional hospital boards should take steps to see that hospital management committees and executive councils are fully informed of the details of any arrangements made for inter-hospital loans and domiciliary use.

HEARD AT HEADQUARTERS

Good at Figures

It was said of the old Insurance Acts Committee that every one of its 40 members was an expert. The same can be said of its successor, the General Medical Services Committee. The Committee spent the whole of a sweltering August day examining the Ministry's report on doctors' remuneration—a report which in fact if not in terms dismisses the claim to a 70% betterment factor. In the course of the day coats came off, and then waistcoats, but mental ardour was undiminished. An actuary of high standing attended the meeting, but several members of the Committee showed that they had a grasp of actuarial principles which would make them competent in that profession should they forsake their own. It was a highly expert discussion in which anyone with "no head for figures" would very soon have been out of his depth. But as a result of that analysis, combined with the first-hand experience of N.H.S. practice, the solid mass of the Ministry's figures began to crumble, and the betterment which it claimed to have been received during the first nine months of the Service looked a very much diminished and tattered figure indeed.

Delays

The long delay in dealing with the question of remuneration must be very tantalizing to the general body of practitioners, and it is natural perhaps for some of them to suppose that it is due to procrastination at Headquarters. Such a judgment is more than usually wide of the mark. Directly the Special Conference of Local Medical Committees (*Supplement*, March 12, p. 129) made its decision on March 3, the document arguing the case (*Supplement*, February 19, p. 83) was sent to the Ministry. But the Ministry would not discuss it until it had obtained figures from the local executive councils about doctors' earnings during the first nine months of the Service. When these returns came in they had to be analysed and summarized. Moreover, some of them were incomplete or obviously erroneous and had to be sent back for local correction and amplification. It was not until August that the returns—a bound volume of 240 foolscap pages—were available for examination and criticism. The Committee was called together at once, some members breaking their August holiday. Even then, although the deputation was all set to meet the Ministry, even within 48 hours, the Ministry was unable to receive it until the third week in September. Whether inevitable or not, and whether blameworthy or not, the delays must be laid at a door in Whitehall and not at a door in Tavistock Square.

Partnerships

One of the surprising things forthcoming from the remuneration tables published by the Ministry is the extent to which the

partnership idea prevails in medicine. In England and Wales actually there are more general practitioners in partnership than working single-handed; in Scotland it is the other way about, but the majority in either part of Great Britain is not great. In England and Wales the number of single-handed practitioners in the National Health Service is given as 7,883 and the number of partners 8,146. In Scotland the single-handed account for 1,202 and the partners for 1,015. In Great Britain as a whole 5,919 are in single-handed practice without an assistant, and 1,166 have one or more assistants. Of the partnerships about half consist of two partners, but one in every eight is a partnership of four or more—the nucleus of a health centre. The partnership idea prevails in medicine to a far greater extent than in any other profession, and it is just a little remarkable, in view of the strong individuality of the average doctor, that he should have submitted himself in such numbers to a voluntary association on which his livelihood depends, and which calls for so much forbearance and give-and-take, and that it should have been in the main so successful.

Questions Answered

Accidents and Emergencies

Q.—*The medical list issued by the London Executive Council, and presumably meant to be exhibited to the public, states that in accident or emergency, if the patient's own doctor or his deputy is not available, treatment can be had from any doctor giving general medical services. The list gives doctors from all over London. Is it not a fact that one is at risk for this type of case only in an area of two miles from one's place of practice, or on one or other side of the Thames, if this is within two miles?*

A.—Normally a practitioner is not required to attend a person at an address other than that at which the patient has been accepted or elsewhere within two miles by road from and on the same side of the river Thames as the practitioner's residence or surgery. Where, however, a patient is absent from the area of his own doctor he is entitled in case of an accident or emergency to apply to the doctor nearest the place where he happens to be.

Hospital Residents' Insurance Contributions

Q.—*What is the position in regard to National Insurance contributions and benefits of hospital residents during the period—say, six weeks—between leaving their old position and obtaining new ones?*

A.—A whole-time salaried hospital officer would be treated for the purposes of the National Insurance Act as an "employed person." As such he would be exempt from the payment of contributions during any week in which he was unemployed and be credited with a contribution for that week), provided he is capable of, and available for, work; has not less than 26 contributions as an employed person paid or credited in respect of the contribution year immediately preceding; and has not less than 10 contributions paid or credited in the 13 weeks immediately preceding the week in question. If he attended at the appropriate employment exchange on each day of unemployment or on such days as he was required so to do, he would be entitled to unemployment benefit; refusal to accept suitable employment offered to him would result in loss of benefit.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.
Non-County Borough Councils.—Dartford, Wallsend.
Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

Correspondence

Doctors and Dentists

SIR,—There were quite a number of letters in recent issues of the *Supplement* dealing with the doctor and dentist question. May I be allowed to answer some of the rather unfair statements, especially those made by Dr. K. V. Deakin (August 27, p. 117)? Being a medical and dental practitioner who some time ago really practised medicine though now slaving as a dentist, I find especially his comparative schedule very amusing though rather poisonous, as it fosters the growing ill feeling between doctors and dentists. Dr. Deakin does not mention the number of doctors in the Service in the Manchester area, nor that of the dentists, as perhaps this point alone may help to clarify the difference of payments made to them. Expenses which he in the doctor's case regards as considerable, and in the dentist's case not so great, amount under present conditions to a percentage of the gross earning considerably higher than Mr. Bevan allows the dentist under his Health Scheme. I would also like Dr. Deakin to have to stand on his legs for up to thirteen hours a day without any more time to sit down than perhaps a lunch break of half an hour, and then perhaps he wouldn't call it ordinary daily hours.

The other points in his schedule show only that in his ideas Dr. Deakin is still living in the 1890's, because otherwise he would know that our practices at present are practically valueless, with no compensation to come on retirement, and also that every sensible dental surgeon regards the prospects as anything but bright, contrary to Dr. Deakin. I am fully aware that the doctor's life is harder than ever. So is the dentist's. Only if both professions stand together, and help each other, then our united prospects may be better. Let us therefore try to find a common platform on which we can fight the injustices of the present Health Scheme.—I am, etc.,

Basingstoke, Hants. K. L. PETER.

SIR,—The report of the General Medical Services Committee on the first year's working of the N.H.S. scheme (*Supplement* August 27, p. 99) makes very sorry reading for the general practitioner. Glasgow's figures approximate to those of Manchester, as pointed out by Dr. K. V. Deakin (p. 117). The average dental remuneration in Glasgow is £3,746, while that of the average general practitioner is £1,340. Even with 50% deduction in the case of dentists and 30% in the case of general practitioners for expenses, the figures are still startling—namely £1,873 net for dental services and £894 for general practitioner services.

One compares with sorrow the relative responsibility in the two cases. The dentist is paid by items of service with practically no responsibility once the patient leaves his surgery, and certainly none when the lesion in question is dealt with. The other assumes continued responsibility, 24 hours a day for 365 days of the year, for all complaints and all illnesses, acting as doctor, psychologist, domestic agency, and family friend. At a time when general practitioners are being overwhelmed with tremendous increases of work under the N.H.S. these relative values give rise to serious anxiety.

The prestige of the general practitioner in this country is in serious danger now. Once that prestige disintegrates (and these figures will never attract the best type into general practice) hospital and consultant service follows rapidly. Professional skill in this country is a pyramid whose wide and firm base is the excellence of its general practitioner service. This is not only a matter of finance, this is the beginning of the end of general practice as this country has known it for generations, unless we take warning now.—I am, etc.,

KATE HARROWER.

SIR,—I feel that I cannot allow the ridiculous letter from Dr. K. V. Deakin (*Supplement*, August 27, p. 117) to pass without comment. As a medically qualified dental surgeon who has experienced some medical practice and is outside the National Health Scheme, I feel that I can speak without bias.

In the first place, a young doctor can start practice with a few pounds worth of equipment against about £2,000 required by the young dental surgeon. I have three surgeries, waiting-room, workroom, etc., with the result that a practice could not be carried on in the average private dwelling, therefore necessitating, as in my case, a separate house costing £230 per annum for rent and rates. I have a weekly wage bill of £37. Has Dr. Deakin anything comparable with that? £50 per month for materials. How absurd of him to suggest that a dentist does not require a telephone or supply a locum in case of illness. Many dentists with a good middle-class practice are finding that expenses amount to nearly two-thirds of the gross takings.

Perhaps if Dr. Deakin would care to exchange certified balance sheets with me, he would think twice before writing such another letter. As a member of the B.M.A. of over thirty years' standing, I am surprised that such a letter is published without comment, as it does not help towards unity with a sister profession in these days when we should all try to pull together.—I am, etc.,

Tunbridge Wells. JAMES MCFARLANE.

SIR,—I feel that I must challenge the remarks of Dr. K. V. Deakin (*Supplement*, August 27, p. 117). I would like to take his table of comparisons point by point.

1. Training for the dentist, "not so long or arduous." I feel that this is a matter for debate.

2. Expenses "not so great." This is a ridiculous statement. Two medical partners need two consulting-rooms, a waiting-room, and one secretary. Two dental partners need a waiting-room, three equipped surgeries, a laboratory, one secretary, two surgery assistants, two or three mechanics, and also an *x*-ray apparatus and all that goes with it.

3. Hours of service for the dentist—"ordinary daily hours." This may be so in city practice but is certainly not so in the smaller town. I am writing this letter at 2.30 p.m. on a Sunday afternoon while an anaesthetic "takes" in my surgery.

4. Car and travelling expenses for the dentist, "unnecessary." Again, as above, it might apply to a city practice so long as the dentist is not connected with any hospital.

5 and 6. Private practice and practices. I would remind Dr. Deakin that compensation for the loss of medical goodwill is officially assured. The dental profession is toying with an imaginative goodwill now, and the intention of the Minister is that we shall transfer our "goodwill" to health centres without any compensation.

7 and 8. It is ridiculous to say that service of dental telephones and supplying of locums is unnecessary. This is a public service—in a small town it is essential, and in a city a practitioner obviously makes arrangements.

9. Dental haemorrhage. This is the work of the dentist anyhow and should be referred to him.

10. Prospects—for the dentist "never brighter." Nearly all dental practitioners have worked harder for the last year than they have ever done in their lives, and it has not been because they want to make money or because they like their work as much as all that.—I am, etc.,

Berkhamsted. C. J. NASH.

SIR,—May I congratulate Dr. K. V. Deakin on his excellent letter (*Supplement*, August 27, p. 117)?

Has not the B.M.A. a Public Relations Department which could bruit his remarks in the popular press? I am certain that the general public have no idea of the low remuneration that their family doctor is paid under the National Health Service for services rendered to them. I wonder if they realize that his remuneration under the National Health Service is very much less than either dentist, chemist, or optician, and that his responsibility is many times greater than any of the aforementioned? Is nothing being done about the very low remuneration of the G.P.?—I am, etc.,

Salford, Lancs. C. M. ISHERWOOD.

Pay-bed Forms

SIR,—Owing to my absence on holiday I have just seen "The Secretary Reports" in the *Supplement* of July 30 (p. 63) in which you reproduce a typical form used in some hospitals to explain to private patients the position with regard to doctor's fees. The authority is Section 5 (2) of the Act. Under this heading the form states, "You will be responsible for paying the doctor's fee up to a maximum of 75 guineas." Note that "doctor" is in the singular. In the next column Para. 3 states "the patient . . . pays the doctor a private fee not exceeding 75 guineas." Again, note the singular.

It seems to me that the Secretary should have expressly pointed out for our information that the use of the singular term "doctor" is wrong. The Statutory Instrument, 1948, No. 1490, is quite definite. It says (p. 3) that "if the total of the maximum charges . . . made by all the medical practitioners concerned in respect of one series of treatments of a patient for relief of the same condition exceeds 75 guineas the amount of the maximum charge . . . shall in the case of each medical practitioner concerned" be reduced in the proportion that 75 guineas bears to the total of the maximum charges.

It is clear from the Second Schedule, containing a list of the maximum charges, that in the case of a major operation the maximum of 75 guineas includes the surgeon's fee and those of the anaesthetist, pathologist, radiologist, and any other practitioner whose services have been utilized. In other words, in the form in question the word "doctor" should have been "doctors."—I am, etc.,

London, W.1. A. RUGG-GUNN.

*** The Secretary writes: The term "doctor" is probably used colloquially in the form quoted for purposes of illustration. The maximum of 75 guineas applies whether treatment is given by one practitioner or by several practitioners.

POINTS FROM LETTERS

Inducement Payments

B.B. writes: I support most heartily Dr. D. N. B. Morrison's contention (*Supplement*, July 23, p. 59). As a practitioner with twenty years' service under the Highlands and Islands medical scheme I have been refused both inducement and basic grants. My mileage is now only 50% of what I received under the other scheme, though I now tend three times the number of patients and car expenses have increased threefold. . . .

B.M.A. War Memorial

Dr. S. G. HAMILTON (Woolacombe, Devon) writes: I should like to associate myself with Dr. W. N. Leak's excellent suggestions (August 6, p. 77) for a War Memorial Room as outlined.

H.M. Forces Appointments

ROYAL NAVY

Surgeon Commander J. Cussen has been placed on the Retired List.

ROYAL NAVAL VOLUNTEER RESERVE

Surgeon Commander D. R. Goodfellow, V.R.D., has been placed on the Retired List.

ARMY

Colonel A. C. Jebb, late R.A.M.C., has retired on retired pay.

ROYAL ARMY MEDICAL CORPS

Colonel F. McKibbin, O.B.E., late R.A.M.C., retired and re-employed, has reverted to the rank of Major at his own request whilst so employed.

Major J. B. Harrower, from Short Service Commission, to be Major.

Major R. T. Wordingham, from Short Service Commission (Specialist), to be Major.

Short Service Commission (Type "B").—Major W. S. Angus, from Emergency Commission, to be Major. Captain M. Wood has retired, receiving a gratuity, and has been granted the honorary rank of Major.

Short Service Commission.—Majors R. H. Smythe and H. A. Ferrante have retired, receiving a gratuity. Captains E. R. Cole

and D. Macdonald have retired, receiving a gratuity, and have been granted the honorary rank of Major.

REGULAR ARMY RESERVE OF OFFICERS

Colonel (Honorary Brigadier) E. P. Allman Smith, O.B.E., M.C., late R.A.M.C., having exceeded the age limit of liability to recall, has ceased to belong to the Reserve of Officers. (Substituted for the notification in a *Supplement* to the *London Gazette* dated July 15.)

ROYAL ARMY MEDICAL CORPS

Captain C. H. Stuart-Harris, from Supplementary Reserve of Officers, to be Major, and has been granted the honorary rank of Colonel.

Captains A. L. D'Abreu and J. M. Black, from Supplementary Reserve of Officers, to be Majors, and have been granted the honorary rank of Lieutenant-Colonel.

Captains L. C-de-R. Epps, A. St. C. Robertson, B. L. Williams, J. R. Blackburne, S. K. C. Clarke, D. H. Sandell, H. A. Dewar, and E. W. Vincent, from Supplementary Reserve of Officers, to be Majors.

Captain F. R. Leblanc, having exceeded the age limit for liability to recall, has ceased to belong to the Reserve of Officers, and has been granted the honorary rank of Major.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Major (acting Colonel) A. L. Crockford, D.S.O., O.B.E., M.C., T.D., has been granted the acting rank of Brigadier.

Captain W. F. Mair to be Major.

Captain R. West to be acting Major.

Lieutenant T. McCarroll, M.C., to be Captain and has been granted the acting rank of Major.

TERRITORIAL ARMY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

Major W. M. Davidson, from Active List, to be Major.

Captain W. F. Mair, from Active List to be Captain, and has been granted the honorary rank of Major.

COLONIAL MEDICAL SERVICE

The following appointments have been announced: M. A. Barnar, M.B., Medical Officer (African), Gold Coast; L. C. Luck, L.R.C.S., Medical Officer, British Guiana; A. J. W. Spitz, M.D., Medical Officer (Temporary), Sierra Leone; J. J. Black, M.B., Senior Medical Officer, Uganda; E. A. Trim, M.D., D.T.M.&H., Assistant Director of Medical Services, Kenya; C. E. W. Hoar, M.B., Pathologist, Nigeria; C. C. Wedderburn, B.M., M.P.H., Assistant Director of Medical Services (Hospital and Personnel), Jamaica.

Association Notices

TUBERCULOSIS AND DISEASES OF THE CHEST GROUP

The inaugural meeting of the Tuberculosis and Diseases of the Chest Group of the Association, whose formation was approved by the Council on June 27, 1949, will be held at B.M.A. House on Friday, Sept. 23, 1949, at 2 p.m.

All those interested in this new group are invited to attend. *Application forms for membership of the group may be* obtained from the Secretary, B.M.A. House, or will be available at the meeting.

SIR CHARLES HASTINGS CLINICAL PRIZE

The Sir Charles Hastings Clinical Prize, which consists of a certificate and a money award of 50 guineas, is again open for competition. The following are the regulations governing the award:

1. The prize is established by the Council of the British Medical Association for the promotion of systematic observation, research, and record in general practice.

2. Any member of the Association who is engaged in general practice is eligible to compete for the prize.

3. The work submitted must include personal observations and experiences collected by the candidate in general practice, and a high order of excellence will be required. If no essay entered is of sufficient merit no award will be made. It is to be noted that candidates in their entries should confine their attention to their own observations in practice rather than to comments on previously published work on the subject, though reference to current literature should not be omitted when it bears directly on their results, their interpretations, and their conclusions.

4. Essays, or whatever form the candidate desires his work to take, must be sent to the British Medical Association House, Tavistock Square, London, W.C.1, not later than Dec. 31, 1949. The prize will be awarded at the Annual General Meeting of the Association to be held in 1950.

5. No study or essay that has been published in the medical press or elsewhere will be considered eligible for the prize, and a contribution offered in one year cannot be accepted in any subsequent year unless it includes evidence of further work. A prizewinner in any year is not eligible for a second award of the prize.

6. If any question arises in reference to the eligibility of the candidate or the admissibility of his or her essay the decision of the Council on any such point shall be final.

7. Preliminary notice of entry for this competition is required, on a form to be obtained from the Secretary.

8. Each essay must be typewritten or printed, must be distinguished by a motto, and must be accompanied by a sealed envelope marked with the same motto and enclosing the candidate's name and address.

9. The writer of the essay to whom the prize is awarded may, on the initiative of the Science Committee, be requested to prepare a paper on the subject for publication in the *British Medical Journal* or for presentation to the appropriate Section of the Annual Meeting of the Association.

10. Inquiries relative to the prize should be addressed to the Secretary.

5	Wed.	Joint Committee of British Medical Association and National Veterinary Medical Association, 2.30 p.m.

Branch and Division Meetings to be Held

NORTH OF ENGLAND BRANCH.—At New Lecture Theatre, Royal Victoria Infirmary, Newcastle-upon-Tyne, Thursday, September 15, 7.15 p.m., Clinical Demonstration by Dr. R. Mason Bolam: "Dermatological Cases"; 8.45 p.m., Address by Dr. G. Brewis: "Present-day Trends in Fevers."

NOTTINGHAM BRANCH.—At 64, St. James's Street, Nottingham, Wednesday, September 14, 8.30 p.m., Agenda: Installation of President, Report of Representatives at A.R.M. at Harrogate, etc.

SHEFFIELD DIVISION.—In General Lecture Room, Sheffield University, Friday, September 16, 8.30 p.m., general meeting. Report by Representatives at A.R.M. at Harrogate.

Meetings of Branches and Divisions

SOUTHERN BRANCH

The 73rd Annual Meeting of the Southern Branch was held in Winchester on July 16. The president, Dr. Howie Wood (Isle of Wight), was in the chair. Fifty-four other members were present.

The report of the Branch Council for the past year was received and approved, as was also the financial statement. The following officers were elected for 1949–50: President, Dr. Marsden Roberts (Winchester); President-elect, Mr. E. Cowper Tamplin (Portsmouth); Vice-presidents, Dr. C. J. Penny (Winchester) and Dr. R. H. Scott (Aldershot and Basingstoke); Honorary Secretary, Dr. R. H. Balfour Barrow (Winchester). Dr. Howie Wood then vacated the chair and invested the new president, Dr. Marsden Roberts, with the president's badge.

Dr. Marsden Roberts first thanked Dr. Howie Wood for his services to the Branch in the past year, and then delivered his presidential address entitled "Rest." He began by telling his audience that when he had made inquiries of the honorary secretary he had learned that many presidents spoke on some aspect of their specialty. As a general practitioner he felt he had no specialty, and when later he mentioned this difficulty to his wife she had told him it always seemed to her that his specialty was "Rest." He felt that his audience might be interested to hear some account of the many Continental motor tours which he had made. These tours were to him the finest form of rest. Dr. Marsden Roberts then told of incidents both grave and gay which had befallen him and his wife on their tours, advising his audience that if they wanted to obtain the most from a holiday they should go abroad.

Subsequently the Branch was accorded a civic reception by the Mayor of Winchester, and the members and their ladies were entertained to tea by the Winchester Division. After tea there was an exhibition of the city plate and charters. Many of the party visited the cathedral, where the Dean of Winchester, Dr. Selwyn, showed the famous "Winchester Bible" and other old manuscripts.

THE RESULTS OF THYMECTOMY IN MYASTHENIA GRAVIS*

BY

GEOFFREY KEYNES, M.D., F.R.C.S.

Emeritus Surgeon, St. Bartholomew's Hospital; Consulting Surgeon, New End Thyroid and Thymus Clinic

It is now eight years since the treatment of myasthenia gravis by thymectomy was first described by Blalock, of Baltimore, and seven and a half years since the first thymectomy for myasthenia was performed in this country. The experiment was initiated by Dr. Arnold Carmichael and his former assistant, Dr. James Carson, and I am proud to say that it was to my hands that they entrusted the performance of the first operation. This was at New End Hospital, in association with Mr. J. E. Piercy, in February, 1942, and the experiment has flourished to such an extent that we have now operated on 155 myasthenic patients, and a considerable number of operations have also been done by other surgeons in this country. It may be admitted, therefore, that enough patients have been treated and a long enough time has elapsed for it to be possible to survey the results in such a way as to form a true idea of the value of the operation, both in its immediate and in its remote effects.

A difficulty in the way of assessment of results is immediately encountered in the well-known tendency of myasthenia gravis to show "spontaneous remissions" of symptoms, for it may be said (and it has been said on several occasions) that the effect of operation, if it seems to be beneficial, may be really no different from what might have occurred spontaneously. It is necessary, therefore, to show that post-operative remissions are both more frequent and more prolonged than could have been expected in the course of nature. It will not, I think, be very hard to do this. First, we must get some idea of the remission pattern in a series of patients who have not had surgical treatment, and here we find help in a paper published last year by Professor A. M. Harvey (1948), of Johns Hopkins University.

He first reviewed a series of 87 patients published by Kennedy and Moersch in 1937. Twenty-seven of these patients had complete remissions, ranging from one month to 16 years; but the majority lasted less than one year, and the average was only 2.2 years. Some of these supposed "complete" remissions were probably, in fact, only partial. Of Professor Harvey's own series of 125 patients, 17 had significant clinical remissions, nine of which lasted over two years. Only one lasted over five years. Professor Harvey has noticed that since the introduction of neostigmine ("prostigmin") therapy spontaneous remissions have been less enduring, and that only one patient so treated had a remission of over two years. This observation is important, because practically all the patients in our series had had neostigmine therapy before operation, and if Professor Harvey is right an insignificant proportion of them would have had lasting remissions. Clearly it would be absurd nowadays to withhold neostigmine therapy on the chance of a few patients having spontaneous remissions. All, or practically all, will have had neostigmine, and the probable incidence of spontaneous remission lasting more than two years would be extremely small.

Four Categories of Results

I have referred on other occasions to the difficulty of assessing results in a disease so extraordinarily variable as myasthenia gravis. In my first communication (Keynes, 1946a) the patients were divided into the four following categories according to results, and the same method is still adopted: (A) Quite well; no symptoms; no neostigmine. (B) Virtually well; minimal symptoms; small dose of neostigmine. (C) Some improvement, often considerable; neostigmine still necessary. (D) No change.

Before considering the numbers that we have placed in these four categories it is necessary to emphasize that those patients who have been found to have thymic tumours have been excluded. The course of the disease and the effect of operation in these patients have been so different from the others that we believe a truer view of the value of operation can be obtained if we first consider only those who were free of tumour formation. Tumours can now nearly always be diagnosed by radiology before operation is undertaken, so that these patients can be set aside for a different plan of action; they therefore form a group for separate study. The incidence of tumours has been found to be 11.6% of all patients, so that the number of patients remaining for assessment is still satisfactory after this deduction has been made.

Patients have been carefully followed up, a few necessarily only by post, since they live in distant parts of the country or in the Dominions. The great majority have been seen personally, and not only by me and by my surgical colleague, Mr. J. E. Piercy. Patients at Queen Square have been seen by Dr. Carmichael and other members of the staff; those at New End by Dr. Raymond Greene; and those at St. Bartholomew's by Dr. Aldren Turner and Dr. Scowen. The number of patients treated privately has been insignificant.

The number of patients available for assessment, after deducting the post-operative deaths (10), the tumours (18), and the few that have not yet been assessed (7), is 120.

The figures for the four categories described I find to be as follows:

(A) 39 (32.5%) (B) 40 (33.3%)
(C) 31 (25.8%) (D) 10 (8.3%)

*A lecture given at the National Hospital for Nervous Diseases, Queen Square, on July 7.

Operative Mortality

The results of the operation can naturally be assessed only among those who have survived the operation—though death is unfortunately one of the possible results, and this must be carefully considered. The total number of patients who died as the immediate result of the operation is 10, but a high proportion of these deaths occurred during the early stages of the experiment, when experience of the operative technique and of the management of patients was small. This is reflected in the fact that five deaths occurred among the first 18 patients and only five in the next 119 operations. If it is fair to take this long consecutive series as the basis, then 4.2% represents the present operative mortality in experienced hands. This is a low figure considering the relatively poor human material with which we have to deal, for myasthenic patients with their narrow margin of respiratory efficiency are unfavourable risks.

The cause of death may be attributed in almost all instances to pulmonary complications; in none, so far, to loss of blood at the operation or afterwards. The pulmonary complications have been occasionally those of an acute myasthenic crisis in which the patients drown in their own secretions; more often they have been attributable to atelectasis of part of a lung or to a flare-up of a pre-existing bronchitis. The risk is always greater in the older patients and in those with coexisting disease—and it is of course the older patients who tend to have the coexisting disease. Thus our death roll included a man of 37 with chronic alcoholism, a woman of 46 with rheumatoid arthritis and cardiac degeneration, and a man of 47 with thyrotoxicosis and cardiac degeneration. Whenever a pulmonary infection becomes established a vicious circle tends to follow, since any acute infection in a myasthenic patient tends to make the myasthenia worse and the response to neostigmine less complete.

Moreover, in the early part of the series we were learning, through experience that was sometimes bitter, how best to perform the operation and how to steer a myasthenic patient through the post-operative period. Before February, 1942, no one in this country had ever performed a total extirpation of the thymus gland. Knowledge of its anatomy was hazy, and some of the information regarding its natural history was erroneous. Blalock's first communication gave very little technical help, though it emphasized the necessity for giving the patients an intravenous drip after operation.

Improvement in Technique

I am not now concerned with details of technique, but naturally our handling of the thymus did improve with experience, and soon it became obvious to us that the prime necessity was to keep the patients dry. To give an intravenous drip to a patient who had not lost a great deal of blood, and who did not suffer from much surgical shock, was unnecessary, and in a patient who tended anyway to produce an excessive bronchial secretion it was actually pernicious. As technique improved we realized the importance of removing the thymus without injury to the pleura, since even temporary collapse of a lung is harmful to a myasthenic patient; also it is easier to ensure pulmonary efficiency if the pleura has not been opened than after any transpleural operation or after accidental opening of the pleura, which may be difficult to close. Nevertheless we still have occasional arguments with thoracic surgeons, who are so accustomed to transpleural operations in non-myasthenic patients that they do not yet appreciate the extra dangers introduced by the presence of myasthenia.

Another strange fact that not all physicians seem to know is that it is dangerous to give a myasthenic patient an enema. Almost invariably the patient will collapse with syncope. This sounds improbable, but we do not doubt that it is a real danger. Early experience on several occasions had warned us, but we had not seen it happen for a long time and had almost come to disbelieve it. We tried to ensure, however, that the ward sisters had fully warned everyone concerned. On one occasion recently the warning, though given in writing, had failed to register. An enema was given, and the patient became unconscious and pulseless. We hope that the experiment will never need to be repeated.

I have referred already to the myasthenic crisis characterized by excessive bronchial secretion, sometimes followed by pulmonary consolidation and death. Occasionally death may be due to a more suddenly fatal cause—complete failure of both heart and respiration.

In April, 1948, a girl aged 16 had travelled from Singapore to London for thymectomy to be performed. Six months previously she had developed symptoms of myasthenia, first noticed as weakness of the arms when brushing her hair. Later the symptoms were mainly bulbar, but varied greatly in severity from time to time. On the voyage to England she had several attacks of dyspnoea, which greatly alarmed her. An operation done in July, 1948, was no more than a skin incision and exploration with a finger in the mediastinum, because at this stage the presence of a tumour was suspected, and the incision was closed. She was then given a course of deep *x*-ray therapy to the thymic area. This had to be stopped halfway through because she became much worse, but it was afterwards completed, and ultimately she greatly improved. She increased in weight and became transformed in appearance, so that the next operation was undertaken with great hopes in December, 1948. A somewhat shrunken thymus not showing any obvious tumour was removed without difficulty and the girl was not immediately affected by the operation. Within two hours, however, there was a sudden failure of peripheral circulation, with extreme pallor. Respiration then ceased and she died in the course of a few minutes. Those who were watching her said that the respiration seemed to stop an appreciable time before the heart had quite failed. At the post-mortem examination no adequate cause for her death could be discovered, and it could only be assumed that this was a form of myasthenic crisis following the disturbance of the operation.

This has been the only instance of death taking place so soon after the operation, and this kind of reaction is clearly exceptional.

The First Patients

Having these facts on the debit side of the account, let me now turn to the pleasanter side and give some account of the post-operative course of the patients who survived. First things come first, and so I must describe the first patient on whom we operated.

This patient was a woman aged 31 who had had symptoms of myasthenia for between three and four years. In February, 1942, she was a patient in the National Hospital, Queen Square, and her symptoms were very severe. Also they were getting worse, together with some mild signs of thyrotoxicosis, and it was thought that her prospects of survival were extremely bad. Thymectomy was therefore suggested, and this was done on February 10, 1942, together with a partial thyroidectomy. Her post-operative course was stormy, though on the fifth day she noticed improvement in nearly all her symptoms, and diplopia, present for several years, had disappeared. Nevertheless this same day she had a severe attack of dyspnoea with much mucus, and almost died. Ten days later she was almost completely well, and neostigmine was reduced to one tablet four-hourly with ephedrine. She had some temporary setbacks after this, but soon returned to her occupation as a land-worker, and has remained well to the present time—that is, for seven and a half years.

The second patient in the series had a thymic tumour and succumbed to the operation.

The third patient was one of the worst with whom we have ever had to deal. He was a man aged 34 who had worked in the National Fire Service. Symptoms of myasthenia had started nine months before we saw him, and had rapidly become worse until he was practically helpless, even with large doses of neostigmine. In addition he had a severe thyrotoxicosis with paroxysmal fibrillation. He was clearly going to die quite soon unless something could be done, and we judged that it would be best to deal with the thyroid gland first. A subtotal thyroidectomy was done on May 2, 1942, and his condition was critical for a few days, with rapid auricular fibrillation. However, he recovered, and after a month's interval a thymectomy was undertaken. He now had no symptoms of hyperthyroidism, but his myasthenia was worse, and he was extremely weak. The operation was done on June 15, 1942, and he stood it well. Some of his symptoms, such as those affecting the voice and swallowing, improved rapidly. The recovery of his skeletal muscles was slow, the delay being partly due to pronounced wasting of the muscles of his thighs and shoulder girdle. He was still taking a small dose of neostigmine two years later, but eventually was able to leave it off entirely, and for the last four years he has been quite well. It is now seven years since the thymectomy was done.

The next patient was a woman aged 44 with a six-years history of myasthenia. A thymectomy was done in May, 1942, and there was great improvement at first. Later she relapsed, and four years after the operation was much the same as before it was done. She died in 1947.

The fifth patient was a sailor aged 22 who had had symptoms of myasthenia for only 11 months, but he was already very ill, and without neostigmine was almost helpless. A thymectomy was done in May, 1942, and during the first 14 days he rapidly improved. A relapse then occurred due to an acute mediastinitis, probably following the liberal scattering of sulphanilamide powder in the mediastinum before it was closed (this was never repeated). Four weeks later he was without symptoms, and neostigmine was no longer given. Since that time he has been quite well.

It therefore seems that three of the first four patients who survived operation have had complete and permanent remissions if upwards of seven years is to be regarded as permanent. The evidence already given regarding the incidence of spontaneous remissions seems to make it unlikely that these recoveries were unconnected with the operation.

The Clinical Picture

Knowledge concerning the function of the thymus gland, whether normal or abnormal, is still very imperfect. We suppose that in removing the thymus we are getting rid of the source of a "curare-like substance" which is discharged into the circulation, though the final proof of this is still lacking. The histology of the gland in myasthenia shows that it is undoubtedly abnormal, and before long we hope to have some light upon the biochemistry of the disease; but even then we are unlikely to know why it is that results of thymectomy are so erratic. This uncertainty has discouraged some operators, including even Blalock himself, from advocating surgery. But the manifestations of the disease itself are just as erratic as the results of surgery, if not more so.

The clinical picture is never exactly the same in any two patients. There are great variations in the muscles affected and so in the mode of onset and in the course of the disease. It may first be noticed in the ocular muscles as diplopia—suddenly appreciated, for instance, during a game of tennis; in the levator muscles as ptosis; in the facial muscles, first noticed when applying lipstick; as difficulty in swallowing; or as weakness in the arms or legs. The disease may advance rapidly or slowly, or it may be stationary for long periods. It may develop in a series of relapses, each being somewhat worse than the preceding one. This highly irregular pattern in the natural history of the disease is reflected in the effect of operation, but, provided that the results, taken broadly, are satisfactory, that is no reason for withholding operation.

Sometimes the effect of the operation is appreciated by the patient with an astonishing promptitude. I have known diplopia, present for years, disappear within 24 hours, never to return. Dysphagia is often abolished within a few days. Often within the first week the patient is aware of a new feeling of vigour in the limbs. The order in which symptoms disappear does not, however, obey any sort of rule. If generalizations are to be made, it may be said that ptosis and ocular palsies are usually the slowest features to disappear; sometimes ocular muscles remain permanently paralysed when all other symptoms have gone, and are then unaffected by neostigmine.

A patient who showed this in an extreme degree was a woman aged 24. She had a 19-months history of fairly severe generalized myasthenia with pronounced ptosis. A thymectomy was done in June, 1945. She made a good recovery except that the ptosis remained, and she afterwards went with her husband to Czechoslovakia. In 1947 she returned to England because, although neostigmine seemed to have some effect on the ptosis, she was unable to obtain the drug. When examined she had no symptoms of myasthenia except the ptosis, and neostigmine had little or no effect on this. She was accordingly given splints for her eyelids, and advised that she no longer needed neostigmine.

Although the ptosis is sometimes persistent, the other facial muscles usually recover well after operation.

In May, 1948, a patient from Australia who was in St. Bartholomew's Hospital gained widespread notoriety in the press as "the girl with the frozen smile." She was a girl aged 16½ with an eight-months history of severe generalized myasthenia showing complete immobility of the facial muscles. Her recovery after thymectomy was almost complete. She still takes a small dose of neostigmine, but her smile has been unfrozen, and this change took place within a fortnight of the operation.

Among those who have undergone complete recovery are a few individuals who are unable, for psychological reasons, entirely to give up taking neostigmine. Their dependence on the drug has over months or years induced a state of mind in which independence of it seems too good to be true, and they still believe it is necessary to take a tablet at irregular intervals, particularly in the evening, when normal fatigue is felt. The most extreme example of this was a girl who would take a tablet on Saturday evenings but at no other time. On inquiry it was found that this was preparatory to going to a dance. Examination of these people will not detect any signs of myasthenia.

It has been suggested by Professor Harvey (1948) that the administration of neostigmine might interfere with the effect of operation in the same way as it appeared to do with the occurrence of spontaneous remissions. In this connexion the following history is of interest.

A woman aged 37 was operated on in September, 1943. She had been the first patient to be treated in this country with neostigmine. She had had symptoms of myasthenia for 17 years, and had received neostigmine therapy for nine years. Though certainly better than before, she has not experienced very great benefit, and now, nearly six years later, she is still in category C.

Nevertheless a general survey of the results with special reference to the period of neostigmine therapy did not reveal any constant relation between them, and there is no justification for basing a prognosis on this evidence.

Failures

It will have been noticed that a small proportion of patients have not undergone any improvement at all. They have not necessarily been those who had severe symptoms of the disease or a long history.

A doctor aged 56 had mild myasthenia for one year, mainly affecting the movements of the lower jaw and lips. The thymus when removed in February, 1946, was quite large, though rather fatty in consistency. The patient's immediate response to the operation was excellent, and he left hospital a fortnight later without any symptoms of myasthenia. Nevertheless a month later he had relapsed to the same myasthenic level as before operation, and there he has remained ever since. He takes 45 mg. of neostigmine daily, with good response.

Another patient who failed to improve after a short history of disease was a man aged 47 who had myasthenic symptoms for two years, especially affecting the ocular muscles. His response to neostigmine was slow. After thymectomy, done in July, 1946, he improved a good deal and was able to return to work in a shop; but 18 months after operation he had relapsed to the same state as before.

A third failure was observed in a woman, aged 26, with moderately severe myasthenia of 15 months' duration. Thymectomy was done in January, 1947, and up to the present time she has not improved at all.

Nevertheless the average age of the failures has been nearly 40, including patients of 39, 41, 47, 56, and 61 years. The youngest was 26. Their histories have also tended to be long, including ones of 5, 8, 12, 12, and 20 years. Since, however, there were four others of 3 months, 1 year, 1½ years, and 2 years, clearly no general inference can be drawn at present. The number is too small for an average length of history in this category to have much meaning.

Age of Patient and Duration of Disease

When we examine the ages of the patients in the other three categories we find that A and B have a considerable proportion of patients of the age of 20 or below, whereas in category C only three are under 20. If the average ages in these categories are calculated, however, the differences are inconsiderable: (A) 28.3 years, (B) 28.4 years, and (C) 32.1 years. It seems, therefore, that the influence of age on the results is less important than at first appeared probable. On the other hand, the calculation of the average duration of the disease is more illuminating: (A) 2 years 2 weeks, (B) 5 years 4½ months, and (C) 7 years 7 months. Here the differences are very striking, and it seems clear that a long history is prejudicial to recovery after operation.

This confirms what I have stated in a previous communication (Keynes, 1946b). It seemed that on the whole the best results were obtained in patients with short histories and the worst in those with long histories, though it was seen that there were exceptions in both directions. It still remains true that the quickest and most complete post-operative remissions are to be expected after short histories, but as time passes it becomes plain that many of the long-history patients will ultimately give unexpectedly good results, although it may take longer to achieve them.

In November, 1948, I operated on two women of this type. One, aged 48, had been bedridden for 12 years; the other, aged 37, had not moved except in a wheel-chair for 27 years. After operation both improved slowly over several months, and, though their remissions are far from complete, both are now able to walk.

Many other patients with histories of five years or over have continued to improve slowly and have been upgraded from category C to B, or even to A.

Another long-term patient was a man aged 38 who, when first seen, had not yet been diagnosed as myasthenic. His appearance, however, was typical, and a test injection of neostigmine, to his surprise, established the diagnosis. He then admitted that he had crept through life only with difficulty, and that his condition had been much the same ever since he could remember anything. He afterwards produced photographs of himself at the ages of 2 and 4½ years, from which it was evident that he had been myasthenic since infancy. His history therefore covered almost 38 years, and when he came under observation he was getting steadily worse, with generalized and bulbar symptoms. He eventually decided to submit to thymectomy in September, 1947, and since that time has steadily though slowly improved. Now, nearly two years after operation, he still needs a small amount of neostigmine, but has been assessed as B, being able to lead a normal life.

Myasthenia Gravis in Infants

The history of this patient introduces the subject of myasthenia gravis in infants, which has specially engaged my interest since I was repeatedly told that the disease was unknown in children. A photograph of the last patient described showed him as apparently suffering from myasthenia at the age of 2; but this did not surprise me, because two years previously I had been asked by Dr. Wyllie to see a patient at Great Ormond Street Hospital for Children.

She was a girl of 4½, who had been admitted apparently moribund, with acute respiratory distress and cyanosis. An experimental injection of neostigmine had an immediate result, and it was then realized that she was suffering from acute myasthenia, symptoms of which had been present for at least a year. I removed the thymus in November, 1945, and she made a good recovery. A year later she still had mild symptoms, but was able to lead a normal life and was described as tireless.

Two months after this incident, which was the first of its kind ever known at Great Ormond Street, a child of 2½ was admitted in a similar state. She was cyanosed and helpless, and again was immediately restored by neostigmine. I operated on this child in February, 1946, and removed what I thought was the whole of the thymus gland. She made a good recovery, but it was only temporary. Four months later she had a severe relapse and quickly died. At necropsy a thymus gland was found equal in size to the specimen I had removed. It was evident that I had removed only one lobe of the gland and had failed to find the other—the only occasion, so far as I know, on which this has happened.

I have not seen another myasthenic infant since this date, though Griffith (1949) described an undiagnosed example. This child had died with symptoms exactly resembling those of the Great Ormond Street children, and it is probable that in the past many children have died of myasthenia, the true diagnosis not having been suspected.

Selection of Patients

Whenever the results of any operative procedure are rather better than preconceived ideas will willingly allow, the charge is made that there has been "selection" of patients. The implication is that unfavourable ones have been eliminated, so that the results seem better than they should be. In the present investigation there has admittedly been some selection of patients, but this has not been exercised by ourselves. It has been through the physicians that most of the patients have, very properly, come to the surgeons, and it is they who have made the selection, which has therefore been in the direction of providing unfavourable rather than favourable material.

Physicians have naturally hesitated to submit to operation patients with only the milder manifestations of myasthenia, such as diplopia, and especially those whose symptoms did

not seem to be progressive. On the other hand, they have not hesitated to recommend operation for patients who were seriously disabled by the disease or whose symptoms were becoming progressively worse. On the surgical side very little selection has been exercised, though a very few patients have been rejected on the ground that operation would clearly be fatal. Sometimes patients have been kept under prolonged observation in order to seize the opportunity of operating when the disease was in a favourable phase.

A patient recently admitted to St. Bartholomew's Hospital under Dr. Scowen had been myasthenic for 16 years. There had been periods of remission, usually partial, but on the whole the disease was progressing, and during the last six years had been very bad indeed. It was found that she responded well to injections of neostigmine, and in six years had had 24,000 of these, many given by her husband, who, being by profession a reader of meters, was accustomed to keeping records. Often the patient herself was too weak to reach for the syringe. She spent two months in Dr. Scowen's ward, and underwent some improvement in this period. When the moment was deemed favourable, the operation was done. This was on June 29, 1949, and she is now improving, the daily dose of neostigmine having been reduced from 270 mg. before operation to 180 mg. at the present time.

Dr. Arnold Carmichael has been so impressed with the results of operation that we have operated at his request on one patient who had no symptoms of myasthenia at all. This is not so odd as it sounds.

The patient, a girl aged 14, had had several attacks of myasthenia, with brief complete remissions between attacks. But Dr. Carmichael was satisfied that each attack was proving a little worse than the one before, and therefore asked for the operation to be done at the safest time—that is, during a remission. This patient has now remained well for six months since the thymectomy was done.

We have operated on one other patient during a remission. This was an Irish youth of 21 who had lost all confidence in himself owing to his relapses, though they were mild. He had developed a myasthenic mentality, which prevented him from following any occupation whatever. Now, two years after thymectomy, he has admitted that he is perfectly well, and he started to work some time ago. Such is the power of surgery over a work-shy neurosis even in a myasthenic Irishman.

It is unnecessary to emphasize the importance of a careful follow-up of thymectomy patients, as this applies to most diseases; but it is worth noting that with the passage of time the results after this operation tend to encourage both surgeon and patients. Many of them undergo a slow improvement over a long period, and very few show the opposite tendency. More patients therefore gain promotion in the ABCD classification than have to be put back, so that each time I have published results they have shown slight improvement on the time before. It must be admitted, however, that there are a few qualifications to be made. Even after apparently complete recovery some of the female patients find that there is a perceptible relapse at the menstrual periods. Secondly, both sexes, although their vigour is normal for ordinary exertions, sometimes find their strength is not completely restored for sustained exertion. It may be, therefore, that the Saturday evening tablet is not entirely psychological in its effect. Thirdly, there seems to be in some patients an irreversible change in one or more ocular muscles and in the levator of the upper lid, the movements being unaffected either by operation or by neostigmine.

Side-issues

It will probably be expected of me to say something on an important side-issue—namely, the relation of myasthenia to thyrotoxicosis. Several writers have thought that there might be some such association, the belief being encouraged by the close anatomical and morphological relationship between the thyroid and the thymus, but we have not found any convincing evidence of this. Only four patients in the whole series of 155 have shown a definite thyroid excess, and in only one was it at all serious. Two of these patients I have already described. A third succumbed to the operation.

The fourth was a woman of 27 who was admitted to hospital with a diagnosis of thyrotoxicosis only, although soon after the onset of this in December, 1946, she had had occasional attacks of diplopia. Ptosis of the left eyelid followed, and then weakness of the left arm and both legs. The whole myasthenic picture then became more pronounced. Mr. J. E. Piercy performed first a subtotal thyroidectomy and then a total thymectomy. At the present time she is free of any symptoms of either disease on three or four tablets of neostigmine a day.

It has been pointed out by Dr. Raymond Greene (1949) that all the ocular muscles responded to neostigmine except the external recti, but that these steadily recovered after the thyroidectomy. The ocular movements therefore showed the mixed effect of myasthenic and thyrotoxic asthenia, each muscle responding to the appropriate treatment. Beyond this we have no evidence to offer. An incidence of four patients with thyrotoxicosis in 155 myasthenics does not seem to afford a basis for any conclusions, though it is perhaps somewhat higher than would be expected from mere probability.

Another side-issue which may be included among "results of operation" is the evidence concerning the supposed enlargement or persistence of the thymus gland in myasthenia. It has seemed to us that the size of the gland bears no relation to the severity or incidence of the disease. Apart from tumours the weight has varied from 3 to 36 g., the average being 15 g. It is now established that the thymus normally persists, and that it does not weigh more in myasthenic patients than in normal people of the same age, among whom the variation is just as wide. The only consistent abnormality has been in the microscopical appearance of the gland, as described by Bratton (1948) and Castleman and Norris (1949). This almost always shows conspicuous lymphoid "germinal centres"; these are not found in the thymus glands of other people.

Tumours of Thymus Gland

As I explained at the beginning, I have considered in the foregoing remarks only the results obtained in the treatment of patients who did not have thymic tumours. I do not now propose to deal in detail with those who had tumours, as they must be the subject of a separate study. It soon became obvious, however, that the presence of a tumour implied a very much worse prognosis. Patients with tumours usually have a short history and severe symptoms which respond slowly and imperfectly to neostigmine. The operation risk is increased by these features as well as by the greatly increased difficulty of removal. The immediate response to operation may be dramatic, but the patients tend to show after a short interval a serious relapse, and the symptoms become irreversible. They have usually soon died with respiratory failure. Primary operation has therefore been very unsuccessful in our hands. We now prefer to treat these patients with preliminary deep *x*-ray therapy, followed by extirpation of the thymus with the tumour if it is possible. A few patients treated in this way have given more encouraging results than those subjected to primary operation.

One patient who had a primary removal of a tumour in January, 1947, followed by deep *x*-ray therapy in June was slowly deteriorating, until Dr. Douglas McAlpine treated him with tetraethyl-pyrophosphate, since when he has steadily improved.

Conclusion

The treatment of myasthenia gravis by thymectomy has been called "empirical," and so it still is in the sense that there are a number of questions to be answered concerning the intimate details of the disease. The connexion between myasthenia and an abnormal thymus gland is now well established, but there is no clue to how or why the gland acquires its abnormal function. The chemistry of the secretion which is producing myasthenia is still quite unknown, and no active principle has yet been isolated.

Fundamental knowledge, such as the truth about the physiology of the neuromuscular junctions, is still lacking, so it is not surprising that understanding of abnormal functions is still defective. Surgery may help to provide an answer to these questions, which are far from being purely academic. In the meantime surgery, with the help of neostigmine, has undoubtedly made a practical advance in being able to alleviate the lot of many of the unfortunate sufferers from myasthenia gravis. There are few more pathetic sights than an otherwise perfectly healthy girl or youth reduced to a state of dependence and physical helplessness, and few more gratifying sights than their dramatic restoration to normal activity, a feat which surgery can now on many occasions claim to have achieved.

Summary

From February, 1942, to July, 1949, 155 patients with myasthenia gravis have been treated by surgical extirpation of the thymus gland.

Of 120 patients who did not have thymic tumours and survived the operation, 79 (65%) have shown a complete or almost complete remission of the symptoms. These could not be accounted for as "spontaneous remissions."

The operative mortality in our hands is at present 4.2%.

The results are influenced by the duration of the disease before operation: the shorter the history the better the results.

Early operation is indicated by the above fact, and by the 11.6% incidence of tumours, the development of which should, if possible, be anticipated.

A statistical study by V. A. Fenger and J. Nielsen[1] shows that in the period 1908–15 the average duration of life of a Danish doctor aged 25 was 3 years shorter than that of his opposite number in the general population. In more recent years this difference has diminished considerably. This study, brought up to 1944, shows that the mortality among Danish doctors is lower than that among the whole population with regard to tuberculosis, cancer, and accidents. But it is higher with regard to suicides, and more than 40% higher with regard to heart disease. A comparison is made with the studies of Dublin and Spiegelman in the U.S.A., and a table is drawn up by the Danes showing how the Danish and American findings compare with each other in respect of each important cause of death.

INCIDENCE OF CROSS-INFECTION IN CHILDREN'S WARDS

BY

A. G. WATKINS, M.D., B.Sc., F.R.C.P.
Paediatrician, Cardiff United Hospitals

AND

E. LEWIS-FANING, B.Sc.Econ., Ph.D.
Statistician, Department of Preventive Medicine, Welsh National School of Medicine

In 1945 the British Paediatric Association began to interest itself in the problem of cross-infection in children's wards in hospitals, and an *ad hoc* committee was set up to consider the matter. Its report was published in the *British Medical Journal* of May 4, 1946 (p. 673). During the committee's deliberations it became obvious that the views and experience of individual paediatricians differed widely. There was not only little information on the incidence of cross-infection but also little evidence of the effect of the common methods used to prevent or control it. The result was a report in very general terms "in the nature of a preliminary discussion," and the collection of evidence on the incidence of cross-infection and the evaluation of methods for its control were left for later investigation. This report is the result.

It is not easy to give an adequate definition of cross-infection in this context, but that suggested by the above-named committee was accepted and used—namely, "To denote any infection acquired by a patient in the hospital environment. Clinically, it is an infection arising during the course of another illness for which the patient was originally admitted to hospital, and may attack the respiratory tract, gastro-intestinal tract, wound, skin, or mucous membrane, or be manifested as one of the specific fevers." This definition places the final onus of diagnosis on the paediatrician, who may or may not have help from bacteriological investigation. This does leave room for a difference of personal opinion, but it was felt that experienced paediatricians would hold relatively uniform views, especially as nearly all those taking part in the investigation had preliminary discussions in committee with their colleagues.

The main objects of the inquiry were to determine: (1) the incidence of cross-infection in children's wards (nurseries for the newborn were excluded); (2) the effect of cross-infection on morbidity and mortality; (3) the part cross-infection played in increasing the length of stay in hospital; and (4) the methods used to prevent cross-infection and their relative efficiency.

Information Sought

Fourteen hospitals were selected as representing a cross-section of children's wards in which patients were under the clinical charge of an experienced paediatrician. The hospitals included examples of children's wards in a general hospital, wards in hospitals for children only, wards in teaching and non-teaching hospitals, and wards taking long-stay cases. In all, the records of 26 different wards were utilized.

Special cards were prepared and issued to each ward for recording the information in respect of every patient admitted. These asked for details of the age, sex, diagnosis on admission, how the child was disposed in the ward on admission and during its stay (e.g., bed in open ward, cubicle), and method of dispersal (e.g., transfer to another ward, transfer to isolation hospital, home). If cross-infection took place its date was to be noted, together with

the suspected source of infection and any relevant bacteriological investigation. Any increased length of stay in the ward as the result of cross-infection was to be estimated, and a special comment was asked for if it was felt that the death of a patient was in any way attributable, either partly or wholly, to cross-infection. The types of cross-infection were divided broadly into: acute specific fevers, upper respiratory infections, lower respiratory infections, gastro-enteritis, and other infections.

A record card was filled in for each child on admission and observations made during the children's stay were dated as at noon of each day. In this way 9,619 cases were covered in the survey. Records were kept from March 1, 1946, to February 28, 1947, but, for reasons to be explained later, analysis was made for only 11 months—i.e., from April 1, 1946, to February 28, 1947.

In addition to the individual patient's record each ward unit was supplied with a questionary form. This asked for information on the following:

Official number of cots in ward.
Upper and lower age limit of children admitted.
Type of case admitted (e.g., medical, surgical, tonsillectomy, skins).
Ward design.—Open ward; length, breadth, height, and distance between cot centres. Number of cubicles, distinguishing single, double, and multiple, giving length, breadth, and height of each cubicle and stating whether it was open or closed.
Quality of ventilation in wards or cubicles.
Method (if any) of isolating new admissions.
Whether a special room is available for dressings.
Method of ward heating.
Number of sluices, lavatories, and wash-basins in each ward or cubicle.
Provision for bed-pan sterilization, napkin disposal, dressings disposal, and refrigerators.
Whether or not a special room and/or special staff is available for preparing feeds.
Method of ward-cleaning—dry sweeping, wet or oiled sweeping, oiled floors, oiled blankets, vacuum-cleaning.
Method of air sterilization (if any).
Status and qualification of staff: ward sister, number of trained nurses, number of student nurses.
Number of nurses per ward—average and minimum per day and night.
Whether "runners" are employed at night.
Whether the nursing staff are immunized against (*a*) diphtheria, (*b*) other infections.
Number of maids per ward.
Whether masks are worn by nurses, doctors, students, and maids.
When masks are worn.
Whether visiting is allowed—how often, how long, how many per bed, and whether children visitors are excluded.
Whether acute fevers are transferred or nursed in the ward.
Any other relevant information.

Data Received

Of the total of 9,619 cases surveyed in the 11 months under review, 679 showed evidence of cross-infection during their hospital stay. This represents an overall incidence (irrespective of length of exposure in hospital) of 7.1%. The frequency of the individual types of infection is shown in Table I.

It is interesting to note that 92 of these children experienced at least two cross-infections and 20 at least three. Tabulation of the acute specific fevers by ward age showed that 23 of the 80 cases of measles were "acquired" before the 10th day, which means that the disease was in the incubation period when the child was admitted to hospital. Similarly three of the five cases of mumps developed before the 21st day in hospital, five of the 24 cases of whooping-cough developed before the 10th day, and three of the 20 cases of chicken-pox developed before the 14th day. It might be objected that these were not strictly examples of cross-infection and should therefore be excluded from analysis. The objection rests entirely on the interpretation of the word "acquired" in the definition of cross-infection: if these were to be excluded many other infections, both of the upper and of the lower respiratory tract, which were not traceable because the length of their incubation is not known would also have to be excluded. It may be added that admission during the incubation period of an infectious disease was in no way confined to one hospital. In point of fact it has been shown that the cross-infection rates at the individual ward ages would have been little affected if these cases had been omitted.

TABLE I

Type of Infection	Total No.	Percentage Distribution
Upper respiratory infections	257	37·8
Acute specific fevers	155	22·8
Measles	80	11·8
Whooping-cough	24	3·5
Chicken-pox	20	2·9
Scarlet fever	14	2·1
Dysentery	11	1·6
Mumps	5	0·7
Diphtheria	1	0·1
Gastro-enteritis	141	20·8
Lower respiratory infections	57	8·4
Other infections	69	10·2
Total	679	

This evidence strengthens the view expressed in the previous report that an essential barrier to cross-infection is a senior medical officer who shall be responsible for all admissions to the ward.

Effects of Cross-infection

On the record card of each patient an estimate was given of the increased length of stay in the ward attributed to cross-infection. No additional stay was occasioned to 65%, up to an additional week was necessary for 17%, up to two weeks for 14%, and up to three or more weeks for 3.6%. The average additional length of stay in the whole series was 4.59 days, and for those 225 children who did have to stay longer their average increased stay was 12 days. This is an important economic aspect of the problem, for in addition to the increased bed occupation in the original hospital there must be added the days spent in an isolation hospital, home, or other institution. This increased occupancy of beds is a strong argument which may be used in favour of administrative or structural measures that may be adopted to lessen cross-infection, as any means which will reduce the length of hospital stay will therefore increase the total annual occupancy of the beds.

Hospital infection may not only increase the length of a child's illness but contribute materially to a fatal issue. We all know of the patient with pyloric stenosis who is successfully operated upon but who dies later from a gastro-enteritis developed whilst in the ward recovering from the operation. Information was sought by the specific question, "Did the observer consider death was attributable in part or whole to cross-infection?" The answer was in the affirmative in 41 of the 50 deaths which occurred in children developing an infection while in hospital (death wholly attributable to cross-infection, 13; death partly attributable to cross-infection, 28), so that of 587 patients who incurred an infection in hospital 7% died wholly or partly because of that infection. As illustrative of deaths wholly due to cross-infection may be cited two patients admitted for

repair of hare-lip, both of whom died of gastro-enteritis. The infections in this group were as follows:

Gastro-enteritis	17 cases (1 Sonne, 1 Flexner Z)
Pneumonia	16 ,,
Pneumonia and enteritis	2 ,,
Upper respiratory infection	2 ,,
Measles	1 case
Meningitis	1 ,,
Staphylococcal pyaemia	1 ,,
Stomatitis	1 ,,
Total:	41 cases

Only seven of these children were over 2 years old, and of the remaining 34 cases no fewer than 24 occurred in babies under 3 months old, thus illustrating the dangers of hospitalization to small babies.

Statistical Problems

The main statistical problems presented were (*a*) to calculate an index suitable for comparing the incidence of cross-infection in the various hospitals and wards; (*b*) to select a suitable standard of comparison; and (*c*) assuming that the incidence would be found to vary between the wards, to determine whether the rates showed any association with the architectural and administrative factors of the ward. One inherent deficiency in the data was that only infections which became manifest during the patient's stay in hospital were recorded. No provision had been made for following patients up, with the result that the number of cross-infections which occurred in hospital but which developed after discharge was unknown, and the value of the inquiry is lessened to that extent. This once again stresses the advisability of giving careful consideration to the statistical aspects when investigations of this nature are in their initial stage.

No index of cross-infection would be adequate which failed to take into account the differing lengths of time each child was exposed to risk—i.e., the duration of stay in hospital. From the information provided the numbers of patients exposed to risk of infection in each ward at each ward-age (i.e., age 1=1 day after entry, age 2=2 days after entry, etc.) were obtained. The numbers of cases occurring in each ward were also tabulated, and by relating the total number of cross-infections which occurred at each age in all the wards combined to the aggregate exposures at the relative ages a cross-infection rate at each ward-age for the aggregate of all wards was obtained. These are the standard rates. In calculating them one difficulty which must be recounted necessitated a change in the initial date of the experience. All children admitted for treatment during the period of the survey are admitted at ward-age 0, but the investigation also covered patients who were in hospital when the inquiry started. To overcome this difficulty it was decided that the experiences should begin on April 1, 1946, instead of March 1. This reduced the length of the inquiry to 11 months, but from the March records the length of stay in hospital previous to April 1 could then be calculated for the majority of children who were in hospital on that day.

The smoothed values of these standard rates (Table II) show that the rate of cross-infection in all hospitals combined rose from 3 per 1,000 in the first four days after entry to 4.9 per 1,000 patients who were in the wards on the 20th–24th days, fell to 3.5 per 1,000 for days 55–59, and was as high as 6.8 per 1,000 for those exposed to risk in days 85–89.

TABLE II.—*Cross-infection Rates (smoothed*) per 1,000 Child-days Exposure (5-day groups); All Wards Combined; Both Sexes. Limited to 91 Days After Admission to Hospital.*

Ward Age Groups	Cross-Infection Rate per 1,000 Exposures	Child-days Exposure in Each 5-day Group
0—	2·96	37,306
5—	3·88	30,065
10—	4·47	20,106
15—	4·79	13,981
20—	4·89	10,655
25—	4·81	8,341
30—	4·61	6,641
35—	4·33	5,355
40—	4·03	4,377
45—	3·75	3,560
50—	3·55	3,030
55—	3·48	2,611
60—	3·58	2,274
65—	3·91	2,056
70—	4·52	1,815
75—	5·46	1,568
80+	6·77	1,383

* $y = 2{\cdot}358 + 0{\cdot}259x - 0{\cdot}00801x^2 + 0{\cdot}0000669x^3$
where y = cross-infection rate, x = ward-age in days.

Standard Cross-infection Ratio

For each ward the number of patients exposed to risk at days 0, 1, 2, 3, 4, etc., was known and the number of cross-infections which would have been expected amongst the numbers exposed to risk at each ward-age if the standard rates (all wards combined) had been effective could be calculated for each ward:

$$\frac{\text{Exposed} \times \text{standard cross-infection rate}}{1{,}000}$$

The numbers expected at each age, aggregated to 91 days or 183 days or 365 days, gave the total number of cross-infections expected in every ward for the respective periods at the standard rates. The number of infections which actually occurred expressed as a percentage of the number expected in the same period provided a comparable index of cross-infection for the different wards. If the actual number was in accordance with expectation the ratio would of course be 100. This index has been termed the "Standard Cross-infection Ratio," because the method of its construction is the same as that of the standardized mortality ratio used by the Registrar-General for comparison of the mortality experienced in different occupations.

When the wards investigated are arranged in order according to the magnitude of the standard cross-infection ratio they may be divided into three groups: those with a high incidence, in which the ratio lies between 140 and 350; those with a moderate incidence of between 60 and 140; and those with a low incidence, below 60, even dropping as low as 29 for a stay of up to 91 days. There are nine wards in the group with a high incidence, eight wards in the moderate group, and nine in the low-incidence group (Table III). It is interesting to observe the extreme

TABLE III.—*Wards Arranged in Order According to the Magnitude of the Standard Cross-infection Ratio, Forming Three Groups with High, Moderate, and Low Incidence*

S.C.R.	Ward	Stay Up to 91 Days
High (140 or over)	Hospital A, Ward 1	350
	,, B, ,, 1 (infants)	205
	,, C, ,, 1 (medical, babies)	190
	,, D, ,, 1 (infants)	188
	,, E, ,, 1 (convalescent)	185
	,, F, ,, 1	148
	,, C, ,, 2	146
	,, G, ,, 1	145
	,, H, ,, 1	140
Moderate (60–140)	,, C, ,, 3 (surgical, babies)	133
	,, I, ,, 1	123
	,, C, ,, 4	111
	,, E, ,, 2 (convalescent)	90
	,, J, ,, 1	88
	,, E, ,, 3 (convalescent)	84
	,, K, ,, 1 (infants)	73
	,, L, ,, 1	72
	,, A, ,, 2	58
	,, M, ,, 1	56
Low (60 or under)	,, K, ,, 2	55
	,, B, ,, 2	49
	,, G, ,, 2	47
	,, L, ,, 2	38
	,, L, ,, 3	34
	,, D, ,, 2	33
	,, N, ,, 1	29

variation in the wards, all of which were under the supervision of expert paediatricians. To note a specific example, one hospital which is modern and with isolation facilities has a high cross-infection rate in its babies' ward but a low one in its older children's ward, both wards being identical in design. The paediatric supervision, both senior and registrar, is the same for both wards, the recording of cross-infections was done by the same individual, and the nursing staff was drawn from the same training school. It is interesting to note that no fewer than four different hospitals are represented in both the high and the low group.

The amount of material for survey was inadequate for calculation of standard cross-infection ratios based entirely on patients who on admission were under 1 year old, 1 to 4 years, 5 to 9 years, and so on. All that was possible was to distinguish 10 wards which excluded entirely children under 1 year of age. Table IV compares the standard cross-infection ratio of those wards with that of wards to which infants were admitted.

TABLE IV

Type of Ward	S.C.R.			
	Low	Moderate	High	Total
Wards excluding infants under 1 year ..	6	3	1	10
Wards admitting infants	3	5	8	16
Total	9	8	9	26

A statistical test showed significant association between the standard cross-infection ratio ($\chi^2=5.8$: $P<0.05$) and the admission of children under 1 year of age. This increased danger in infancy is a fact well known to all practising paediatricians.

This relation between age and cross-infection is the only "statistically significant" result of our attempt to correlate incidence with environmental influences. Other factors which were statistically investigated but gave no conclusive results were: type of case admitted (surgical, medical, etc.); relation between standard cross-infection ratio and architectural features of cubicles; average square feet per cot; quality of ventilation; employment of "runners"; method of ward-cleaning; and patients' visitors and frequency of visiting-days. (Because of their negative findings these analyses are not recorded in full.) The unit for these analyses was the ward, and with only 26 units it was hardly to be expected that many significant relationships would appear.

The difference between the wards with regard to cross-infection remains difficult to explain fully. There is no doubt that imponderables must play an important part—namely, the quality of the medical and, particularly in this problem, the nursing care. We have noticed that there has been an increase in infection when there has been a change of nursing staff, though we have no figures to support this, and it would seem that there is still a tendency to understaff babies' wards at night. Thus all the careful work done by the day staff can be undone through a shortage of nurses at night to do the common tasks with adequate care and time.

Another factor which is difficult to assess is the question of immunity of a child admitted to a strange bacterial or viral environment. Bacteriological studies were not undertaken in this review except in a few instances, for in one of the commonest of the infections, gastro-enteritis, there is no specific organism to act as an indicator. It is well known that babies are slow in acquiring an immunity reaction, and this may well be a factor in the increased infection found in the very young.

Conclusion

On the whole we feel that this inquiry, which entailed a great deal of work for many people, has been disappointing in that it has not resulted in our being able to give advice to hospital planners on the value of the common architectural practices in preventing cross-infection. Further inquiry on these matters which will stand up to statistical scrutiny is desirable. We feel, however, that we have at least obtained some figures that are of interest if only in showing for the first time the extent of cross-infection in a sample of hospital wards in this country and in drawing attention not only to its prevalence but also to its dangers.

It should be recalled that the wards chosen were all under expert paediatric supervision and therefore the number of cross-infections was, or should have been, minimal. However, the very fact of the inquiry taking place in a ward helped to draw attention to the condition and so in itself may have reduced the incidence a little. If, then, hospitals of this status have a cross-infection rate as high as 7% it may be suspected that other hospitals with less facilities and less expert staff have a higher rate.

In this respect it has been interesting to note the reaction in some hospitals visited outside the scope of this inquiry to the question, "How much are you troubled by cross-infection?" In many instances the reply has been given that cross-infection has never occurred, from which it seems likely that the problem has not been acknowledged or recognized. If, then, this paper can do something to interest those responsible for the care of children in hospital in this aspect of their work we feel we may have accomplished something of value.

Summary

Records of all children admitted to hospital during the year March 1, 1946, to February 28, 1947, were provided by 26 children's wards in 14 hospitals in Great Britain. From these records information was obtained as follows: (*a*) The overall incidence of cross-infection in 9,619 admissions was 7.1%. (*b*) The average length of increased stay in hospital of these cases that developed a cross-infection was 12 days. (*c*) In 41 children death was attributable partly or wholly to cross-infection. (*d*) An index for the rate of cross-infection was calculated for each ward (standard cross-infection ratio) and was found to vary widely for the different wards even within the same hospital. (*e*) Attempts were made to correlate factors which might be related to the variations, which included ward architecture, equipment, nursing, staffing, visitors, type of case admitted, and the age of the children. The only "significant" finding was that cross-infection was commoner in wards which admitted infants.

The data on which this paper is based have been produced by the helpful co-operation of many sisters and registrars in the hospitals concerned and of the paediatricians who had the children under their care. The following hospital centres have contributed, and we are grateful to all who have helped: Belfast, Birmingham, Cardiff, Glasgow, Guy's, Great Ormond Street (including Tadworth), King's College, Leeds, Liverpool, Newcastle-upon-Tyne, St. Bartholomew's, and Warwick.

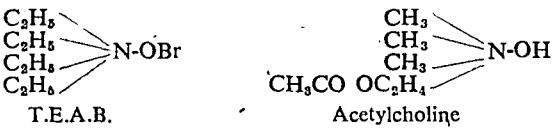
We wish to acknowledge many helpful suggestions made by Professor R. M. F. Picken during the course of the analysis. Our thanks are due to Miss Kathleen Davies and Miss Betty Goode, on whom has fallen the burden of the heavy tabulation and computing work, not all of which has been produced in this paper. We are also indebted to the members of the *ad hoc* Committee of the British Paediatric Association on Cross-infection for much valuable advice in the carrying out of this inquiry, and to the British Paediatric Association for a grant towards the computing expenses.

EFFECT OF TETRAETHYLAMMONIUM BROMIDE ON GASTRIC SECRETION AND MOTILITY

BY

I. R. MacDONALD, M.B., Ch.B.

AND



A. N. SMITH, M.B., Ch.B.

Formerly House-surgeons, Western Infirmary, Glasgow

Tetraethylammonium bromide (T.E.A.B.) is known to produce a blockade of the autonomic nervous system, and has been used with this object in the investigation of peripheral vascular disease. The purpose of this paper is to examine its effects on the secretory and motor functions of the stomach.

Pharmacology

The site of action of tetra-alkyl-ammonium compounds is at the ganglionic synapses of the autonomic nervous system, where a blocking effect was first demonstrated by Marshall (1913). T.E.A.B. is a synthetic compound produced by the substitution of four ethyl groups in the ammonium radical of ammonium hydroxide. The chemical relationship of the drug to acetylcholine is:

T.E.A.B. Acetylcholine

The site of action of the two compounds is the same and is probably determined by their basic structural relationship; side-chain variants determine their pharmacologically different effects. The blocking effect of T.E.A.B. is probably due to the fact that the drug can replace acetylcholine in the neurohumoral chain at the autonomic synapse, thus excluding it. The transience of its action is probably also due to its similarity to acetylcholine, which is destroyed by cholinesterase.

The pharmacological effects are twofold. Sympathetic blockade leads to release of peripheral vasoconstrictor tone, a fall in blood pressure, and an increase in pulse rate. There is increased blood flow to the extremities, with increased skin temperature. Sweating is inhibited. Parasympathetic blockade leads to inhibition of gastric secretion and motility, inhibition of salivation, paralysis of accommodation, and transient impairment of the power to urinate or defaecate.

Side-effects are noted as follows. After moderate doses (less than 500 mg. intravenously or 20 mg. per kg. of body weight intramuscularly) there is a metallic taste in the mouth, with a sensation of warmth and flushing, transient peripheral numbness, light-headedness, loss of accommodation, and transient difficulty in urination or defaecation. After large doses ptosis, weakness, or even severe collapse may occur. While these severe manifestations are rare, the commoner side-effects make out-patient administration impracticable.

Effect of T.E.A.B. on Gastric Secretion

Published work on the effect of T.E.A.B. on gastric function comes mostly from America. Zweig *et al.* (1948) found that in normal subjects the gastric motility was completely inhibited for a total period of 45–100 minutes after intravenous injection. Unstimulated secretion was reduced by 85% and histamine-stimulated secretion by 70%; on the contrary, Neligh *et al.* (1947) noted no effect on histamine-stimulated secretion. Brown *et al.* (1948) demonstrated, in duodenal ulcer patients, inhibition of gastric motility and abolition of insulin-stimulated secretion. Ferrer (1948) reported effective reduction of excessive night secretion in patients with peptic ulcer.

1. *Studies by Alcohol Test Meals.*—We have studied the effect of T.E.A.B. on gastric secretion following an alcohol test meal in 20 cases (17 men and three women, eight of them suffering from duodenal ulcer). The method was as follows:

The patients were starved over nine hours, a Ryle's tube was passed at the end of this period and the fasting juice aspirated. Then 50 ml. of 7% alcohol was given and specimens were removed from the stomach every 15 minutes for one and a half hours and titrated. The following day, at the same hour, this procedure was repeated, but in addition 1 g. of T.E.A.B. was given intramuscularly as a 10% solution half an hour before the start of the test meal. The patients were interrogated regarding symptoms following T.E.A.B. administration. Blood-pressure readings were taken throughout. The average values for the 20 test meals are shown in Fig. 1. There is an average reduction of 5–10 clinical units of free HCl. Some reduction in the free HCl was noted in every case. In several the reduction was of the order of 20 units.

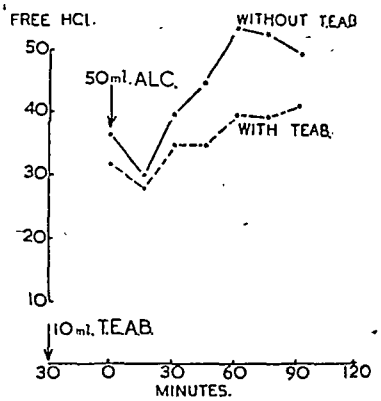


FIG. 1.—Effect of T.E.A.B. on gastric secretion after an alcohol test meal (20 cases, average values).

2. *Studies after Insulin Stimulation of Secretion.*—Because of the known pharmacological effect of T.E.A.B. in blocking vagus synapses it was of interest to investigate its action after the administration of insulin. In 1943 Hollander observed copious acid secretion in the gastric pouch of dogs in which he had induced hypoglycaemia; he found a pronounced acid secretion so long as the vagus supply to the stomach was intact and cessation on complete severance of all vagal fibres. This observation led to the development of the insulin test for vagus activity. It was employed as follows in our cases.

The alcohol test-meal technique already described was followed in 10 patients, with the modification that one and a half hours after the meal in each case 20 units of soluble insulin

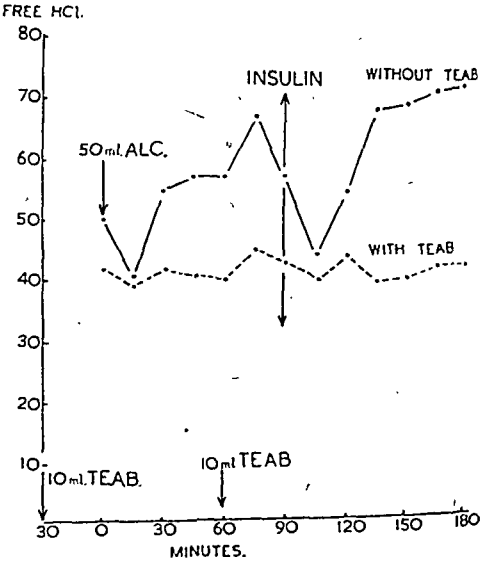

FIG. 2.—Effect of T.E.A.B. on gastric secretion after administration of insulin (10 cases, average values).

was given intramuscularly. A similar procedure was adopted in the same patients (on a subsequent occasion) after the administration of T.E.A.B. (The patients were all adults, eight males and two females, four of them suffering from duodenal ulcer.) The blood sugar in all cases fell below 55 mg. per 100 ml. The symptoms noted included weakness, hunger, and emptiness. The average of the 10 test meals is shown in Fig. 2. It will be seen that after T.E.A.B. the production of insulin hypoglycaemia failed to stimulate the secretion of gastric juice.

3. *Studies after Histamine Stimulation of Secretion.*—The response of the stomach to administration of histamine was studied by the method already described for insulin, an injection of 1 mg. of histamine being given at the end of 1½ hours in each case. In view of the effect of histamine on blood pressure no patient was used in this series whose blood pressure fell below 100 mm. Hg as a result of T.E.A.B. The average results of the 10 experiments (all adults — nine males, one female, including four cases of duodenal ulcer) are recorded over the entire three-hour period (*Fig.* 3). It will be seen that after T.E.A.B. the injection of histamine stimulated the secretion of gastric juice, but the response was not so great as in the control series.

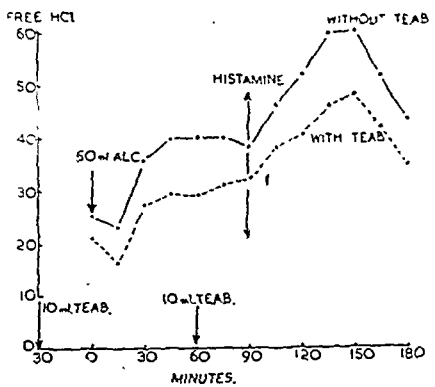

FIG. 3.—Effect of T.E.A.B. on gastric secretion after histamine stimulation (10 cases, average values).

4. *Studies on Spontaneous Night Secretion.*—Much attention has recently been devoted to the secretion of the stomach during interdigestive phases, and particularly at night. It is claimed that the nocturnal secretion is large in volume and highly acid, and that this unbuffered secretion expelled rapidly into the duodenum is of importance in the production of duodenal ulcer. Investigations of the action of T.E.A.B. upon the nocturnal secretion in 10 patients were made as follows.

The patients had nothing to eat or drink after 5 p.m. A duodenal tube with multiple perforations at its tip was passed at 8 p.m., the stomach emptied of its contents, and the secretion aspirated till 8 a.m. by means of constant suction set up by means of an electric pump. Narcotics were withheld. The following evening the experiment was repeated, giving 1 g. of T.E.A.B. four-hourly to a total of 3 g.

Night Secretion Tests (8 p.m.–8 a.m. Continuous Suction). Total Dosage = 3 g. of T.E.A.B.

Without T.E.A.B.			With T.E.A.B.			Average Reduction in Milli-equivalents/Hr.
Volume	Free HCl	Total Acid	Volume	Free HCl	Total Acid	
630	36	57	400	12·5	26·5	79%
105	12	22	55	0	6	100%
595	42	58	400	20	34	70%
750	56	66	305	33	46	76%
410	36	52	300	12	28	75%
640	9	19	274	9	30	60%
740	48	60	480	20	28	69%
1,170	28	34	372	15	33	84%
220	14	32	104	0	6	100%
692	13	22	165	4	24	91%

In 10 cases the volume of secretion was reduced, as was the acidity. The accompanying Table shows that T.E.A.B. brought about an average reduction of 309 ml. in the volume of the night secretion and a reduction of 80% in milli-equivalents per hour of the night secretion. All patients were cases of duodenal ulcer with severe symptoms. None complained of dyspepsia during the administration of T.E.A.B.

Effect of T.E.A.B. on Gastric Motor Functions

This was studied in five patients by means of gastrograms according to the technique described by Kay (1947). After a 12-hour fast the patients (all of whom were cases of duodenal ulcer proved later at operation) swallowed two Ryle tubes fastened together, one having an inflatable balloon attached at its tip.

The balloon was inflated to a standard pressure of 5–10 ml. of water and the column of air was connected to a tambour kymograph unit recording variations in intragastric pressure; the other Ryle tube may be used for aspiration of secretion or performance of the "water test" (Kay, 1947).

In normal individuals the gastrogram has four components (Johnson, 1948): (1) Postural tonus, characteristic of hollow viscera, fairly constant and independent of its degree of distension. (2) Tonus waves: these are regular gentle undulations of postural tone, which may be peristaltic in nature, with a frequency of three a minute. (3) True gastric contractions which are spastic contractions of the whole stomach, considerably increasing intragastric pressure. They are represented by sharp-topped waves lasting 30 seconds, and occur in normal individuals in bursts at intervals of 1½–2 hours with a frequency of 1–2 minutes. They are present in hunger pains and are greatly increased in amplitude and frequency in duodenal ulcer patients. (4) Cardio-respiratory effects: these are frequent small oscillations superimposed on the above intrinsic waves. They are due to respiratory movements of the diaphragm and cardiac pulsations; they occur with a frequency of 20 a minute. In five patients showing frequent true gastric contractions after a control period of 20 minutes, 1 g of T.E.A.B. was injected intramuscularly. After a latent period of 15–30 minutes tonus waves and true gastric contractions were abolished and postural tonus diminished: the effect persisted for 1–1½ hours, tonus waves returning before gastric contractions. There is a striking similarity between the gastrogram shown and that following vagotomy: in four of five patients this inhibition of vagal activity was found, the remaining case showing for 1½ hours diminished frequency, amplitude, and duration of contractions (Fig. 4).

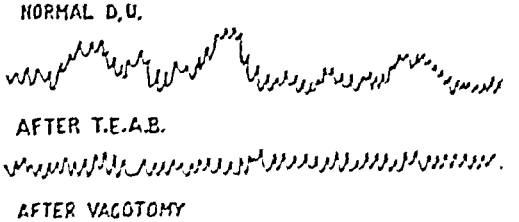

FIG. 4.—Gastrograms in normal duodenal ulcer, after injection of T.E.A.B., and after vagotomy.

Discussion

The administration of T.E.A.B. leads to a slight fall in gastric acidity as estimated by the alcohol test meal. After T.E.A.B. the induction of insulin hypoglycaemia fails to stimulate a rise in gastric acidity. This indicates the presence of vagal blockade and is in keeping with the known action of the drug. It can be assumed that such secretion as occurs after T.E.A.B. is due to the chemical mechanism of gastric secretion. It is interesting to note that after T.E.A.B. the injection of histamine does stimulate gastric secretion, albeit less than normally. This is interesting on account of the fact that histamine acts directly on the oxyntic cells, and so the reduction in acidity in this case cannot be due to an autonomic blockade. Hollander (1944) asserts that the oxyntic cells secrete acid of a constant strength; but if on histamine stimulation they secrete into a stomach which is comparatively amotile there will result a fair degree of buffering and dilution by alkaline and mucoid elements. This fall in acidity may therefore be attributed to retention, to which Johnson ascribes the same effect following vagotomy. He points out that in the amotile stomach there is difficulty in evacuating serial specimens completely, so that dilution of secretion occurs.

The reduction in night secretion is interesting. Because of the motility effect, it could be held that it was in part due to regurgitation of duodenal contents through a relaxed pylorus. A few experiments were abandoned because of bile-staining of the juices drained off; on the other hand, the 10 cases reported were free from bile in the suction specimen, and the volume in the 12-hour specimen after T.E.A.B. was less than that taken off the previous evening.

The average reduction in milli-equivalents per hour was 80%, comparing not unfavourably with 90% following anatomical section of the vagus.

The motility effect has been shown to be similar to that following vagotomy; but T.E.A.B., as well as inhibiting the parasympathetic supply of the stomach, might be expected to effect gastric function in some way by its action on the sympathetic. There are several records of the effect of splanchnic section on gastric secretion in man and animals. Brown (1933) could find no demonstrable change in free or combined acidity following complete removal of the sympathetic chain or coeliac ganglia in cats, and Ray (1942) investigated and found no change in gastric acidity after bilateral sympathectomy.

It has been claimed by Little *et al.* (1947) that T.E.A.B. is effective in preventing or modifying the course of peptic ulcer produced experimentally in animals. In view of its effects on the gastric secretion and motility, and particularly on the volume and acidity of the nocturnal juice, the hope was raised that it might be of value in the treatment of peptic ulcer in man. It is perhaps worthy of note that all 10 patients submitted to repeated injections of T.E.A.B. were free from pain during the progress of the experiment, whereas previously they had had incapacitating symptoms. T.E.A.B. has, however, certain practical disadvantages, especially in requiring to be given by injection and in giving rise to unpleasant subjective symptoms. It remains for future research to find a means of prolonging its action and minimizing its side-effects.

Summary

The chemistry and pharmacology of T.E.A.B. are described.

T.E.A.B. produced a slight fall in gastric acidity in the secretory response to an alcohol test meal.

It negatived the secretory response to hypoglycaemia.

It reduced the response to histamine.

It reduced the volume and acidity of the 12-hour spontaneous night secretion.

It produced a vagotomy-like effect on gastric motility.

Its effect on the cephalic and humoral phases of secretion is discussed after its use in 10 patients submitted to insulin and histamine stimulations respectively. The changes in the concentration of the night secretion in 10 ulcer patients and the effects on motility in five ulcer patients are discussed; a comparison is drawn with that following vagotomy. Its disadvantages are enumerated. Experimental use in peptic ulceration in animals is mentioned and suggestions are made for further use.

We are indebted to Professor C. F. W. Illingworth (under whose guidance this work was done) for help in the preparation of this paper. We wish to thank Mr. A. W. Kay for facilities in recording gastric motility.

NITROGEN MUSTARD THERAPY

WITH SPECIAL REFERENCE TO HODGKIN'S DISEASE

BY

J. D. N. NABARRO, M.D., M.R.C.P.

Medical Registrar, University College Hospital

Therapeutic trials with the nitrogen mustards in cases of neoplastic disease were started in the United States in 1942. Rhoads (1946) published the first analysis of results obtained, and many further reports have appeared since. Experiences in this country have been given by ApThomas and Cullumbine (1947), Wilkinson and Fletcher (1947), ApThomas (1948), Boyland *et al.* (1948), and Watson and Pemberton (1948). These reports make no claim that the treatment is any more than palliative. The best results have been obtained in cases of Hodgkin's disease, and moderate but variable remissions in other lymphomata and lymphosarcoma, chronic leukaemia, polycythaemia vera, and mycosis fungoides. In carcinomatous conditions the results have been disappointing except in bronchial growths, where in some cases transient benefit has followed treatment. In April, 1946, a trial supply of the "bis" compound was received. As it is now generally available, this interim report summarizing the benefits and dangers attending its use is being published.

Dosage and Method of Administration

The amount of the drug that can be given is limited by the action on the bone marrow, and the American workers recommended that in a standard course the total dose of the "bis" derivative hydrochloride should be 0.4 mg. per kg. of body weight. This was divided into four doses of 0.1 mg. per kg. given intravenously on consecutive days. The vein used for the injection often becomes thrombosed, and to reduce the demand for veins trials were made with fewer but larger injections. This also

had the advantage that the vomiting which followed most injections was repeated on fewer occasions and the course was completed more quickly. When a patient is being treated for the first time it is advisable to start with a small dose—0.1 mg. per kg. or even less in debilitated subjects—and if the response is satisfactory the course may be completed by two further injections of 0.15 mg. per kg. In subsequent courses two injections of 0.2 mg. per kg. are given, or, if it is decided to give maintenance injections at regular intervals, 0.2 mg. per kg. once only, every four to eight weeks. The maximum single dose given to any patient was 12.5 mg. It was found that the best time to give the injections was in the morning after a light breakfast. The question of the time interval that must be allowed before a course is repeated will be discussed later in relation to toxic effects on the bone marrow.

The white crystalline salt is dissolved in about 10 ml. of sterile saline immediately before injection. It must not be allowed to stand after being dissolved, as it undergoes hydrolysis and becomes inactive. All-glass eccentric-nozzle syringes have been used with a size 17 needle; the injection may be given as quickly as the size of the needle permits. It was found that when the injection was made direct into the vein thrombosis occurred in about half the cases. This may lead to considerable difficulty if repeated courses are needed, and it is also advisable to retain one large vein in case blood transfusion is required later. An alternative technique of administration is to inject the drug into the tubing of a running saline drip, by which the incidence of thrombosis is much reduced. When a patient receives the drug for the first time, direct injection may be used, but if widespread thrombosis follows and further courses are likely to be indicated it is wiser to change to the drip-tube method. Veins partly occluded by tumour masses should be avoided. If any of the solution escapes into the subcutaneous tissue, oedema, redness, and discomfort appear in about 24 hours and may last several weeks.

Results

In many of the published reports success has been claimed if any regression of the tumour masses occurred after treatment. The regression may, however, be so slight or so transient as to be of no practical value, and may be unaccompanied by any improvement in the general condition. Stricter criteria have therefore been adopted in assessing this series. The results have been described as conspicuous benefit, moderate benefit, or failure. Conspicuous benefit is considered to have been obtained if a previously incapacitated patient is able to leave hospital and return to and continue in his normal occupation for at least three months; moderate benefit—a remission of similar duration in which the patient is able to leave hospital and be about his home; and anything less than this—a failure. Thirty-eight patients have been treated and a total of 61 courses and a number of maintenance injections have been given. The cases treated and the results obtained are shown in Tables I and II.

TABLE I.—*Summary of Cases Treated and Results*

Nature of Case	Number of Cases	Result		
		Conspicuous Benefit	Moderate Benefit	Failure
Hodgkin's disease:				
Previously untreated	6	2	1	3
Previously treated by surgery	1	1	0	0
Previously treated by *x* rays	14	2	0	12
Malignant lymphoma	3	0	1	2
Acute lymphatic leukaemia	1	0	0	1
Chronic lymphatic leukaemia	1	0	0	1
Lymphatic leukaemia with lymphoblastic lymphoma	1	0	0	1
Multiple myeloma	1	0	0	1
Carcinoma of bronchus	5	0	0	5
Carcinoma of rectum	1	0	0	1
Mycosis fungoides	3	0	1	2
Lipomelanic reticulosis	1	0	0	1

TABLE II.—*Duration of Remission in Cases showing Benefit*

Case No.	Nature of Case	Course No.	Duration of Remission	Classification	Remarks
3	Hodgkin's disease	N.M.1	5 months	Conspicuous benefit

		N.M.2-3	3 ,,		

N.M. = Nitrogen mustard—the "bis" compound

Cases of Hodgkin's Disease that had not received Previous X-Ray Therapy.—In a group of six cases there were two in which conspicuous benefit was obtained. Both had visceral deposits, and one of them (Case 3) had fever and anaemia and the other (Case 5) amyloidosis and hypoproteinaemia. Case 19, with lymphadenopathy, fever, and anaemia, had a remission after the first course of four months during which she was able to leave hospital and do some of her housework; a second course, however, produced less improvement and deep *x*-ray therapy was given. The three failures included one with anaemia, fever, and hepatosplenomegaly, which showed no response at all: one with axillary lymphadenopathy, which rapidly recurred: and one in which enlarged mediastinal glands showed slight regression only. The last two cases were examples of the commonest type of Hodgkin's disease, which presents with localized glandular masses, and on account of the poor results obtained here, and reported by others, no further cases of this type were given nitrogen mustard as the initial treatment. A further case (No. 6) had a large mass of glands excised from the side of the neck. Microscopical examination showed Hodgkin's disease, and a course of nitrogen mustard was given. The patient has remained well and been gaining weight since (21 months).

Cases of Hodgkin's Disease Treated Initially with X Rays.—The 14 patients who were treated initially with deep *x* rays and subsequently given nitrogen mustard fall broadly into two groups. The first (four cases, one conspicuous benefit (No. 24), three failures) had had repeated recurrences in one group of glands and the condition of the skin precluded further irradiation. The disease in patients of the second group had, after a slow or rapid evolution, apparently reached the terminal stage. In some, numerous deposits of Hodgkin's tissue were rapidly appearing in different sites; in others, despite such evidence of activity as fever or anaemia, there were no deposits suitable for local *x*-ray treatment. (Ten cases, one conspicuous benefit (No. 9), nine failures.) In two cases of the more acute type in which the remissions produced by irradiation were of brief duration, those following nitrogen mustard were equally disappointing.

Results in Other Conditions.—There were three cases of malignant lymphomata of other types: a reticulosarcoma which showed no response, a very primitive lymphoma in which dramatic but incomplete and transient regression occurred, and a slow-growing lymphoblastic lymphoma in which there was moderate benefit (Case 25). In the cases of carcinoma of the bronchus treatment failed to relieve either chest or nerve-root pains. The three cases of mycosis fungoides were all of long standing, and although an incomplete remission of reasonable duration was obtained in one the results were disappointing.

Complications and Side-effects of Nitrogen Mustard Therapy

The three most important of these are: changes in the blood, vomiting, and venous thrombosis at the site of injection. The last-named has already been discussed.

The white cell levels changed in nearly all cases. In the first few days a transient increase of neutrophils and reduction of lymphocytes was usually found; much more important, however, was the granulopenia which followed —maximal at the beginning of the second week and returning to normal levels about the fourth. Complete absence of polymorphs from the peripheral blood occurred in two patients. The first had an acute malignant lymphoma, which showed partial regression after a course of treatment. As a desperate remedy this was repeated after two weeks, but the patient died one week later and the agranulocytosis which had developed was probably a contributory factor. The second patient had Hodgkin's disease, and derived some benefit from a course of nitrogen mustard, which was repeated after two months. Typical agranulocytic angina followed, but intensive penicillin therapy controlled the infection and white cells reappeared in the peripheral blood. He was later given a blood transfusion and was able to leave hospital, but he died at home shortly afterwards. In neither of these patients was the haematological response to the first course suggestive of unusual sensitivity, and the pre-treatment levels of polymorphs and lymphocytes were within normal limits in the first case and in the second were 3,900 and 260 per c.mm. respectively.

The depression of the white cell count is the limiting factor when the repetition of courses after a short interval is being considered. In the case mentioned above a second course was given as a desperate remedy after two weeks; on five other occasions a second course was given after four weeks without untoward result. With further experience this procedure was rarely adopted. If the clinical response to the first course is transient or incomplete little benefit may be expected from re-treatment at so short an interval; and if the patient is still in remission it is better to await evidence of renewed activity before undertaking a further course or starting maintenance therapy.

The use of nitrogen mustard therapy in cases of Hodgkin's disease with severe leucopenia has been discussed by Rosenthal (1948), who recommended splenectomy prior to treatment. The following case is of interest in this respect.

Case 5.—Man aged 26. Onset in June, 1944, with fever and enlarged axillary glands. Biopsy in January, 1947, showed Hodgkin's disease with amyloidosis; there were hepatomegaly, ascites, and oedema of the legs; Congo-red test gave 100% absorption, and serum albumin was 2.1 g. %. Two courses of nitrogen mustard at a four-weeks interval (26 mg. and 32 mg.) gave a good remission of twelve months' duration. In March, 1948, a relapse was treated with a further course of 25 mg., again with good response. In July a further relapse occurred and the absolute polymorph count was 128 per c.mm. Sternal puncture showed that 73% of cells were of the granulocyte series, and therefore a further course of 25 mg. was given, which led to a steady rise in polymorph counts. He received four maintenance injections of 12.5 mg. each and remained at work until December, 1948. He died in January, 1949.

The red cells were not usually affected when early cases of Hodgkin's disease were treated, unless the patient was anaemic, in which case a spontaneous rise to normal levels accompanied a good clinical response (Case 3). In terminal cases this treatment may produce extreme depression of the haemoglobin level, although it is difficult to decide to what extent this is due to the treatment rather than to the evolution of the disease. In the following case treatment was followed by an immediate improvement, but in the second week the patient became very anaemic, presumably as a result of the action of the drug on the bone marrow. The patient was, however, kept alive by blood transfusion and subsequently had a satisfactory remission

Case 9.—Man aged 42. Onset August, 1944, with cervical lymphadenopathy; biopsy showed Hodgkin's disease, and a course of deep *x*-ray therapy was given. From April, 1946, to April, 1947, he had recurrent bouts of fever, for which he received further *x*-ray treatments and blood transfusions. He was then admitted to hospital, when examination showed him to be emaciated, febrile, and anaemic (Hb 60%), although there were no localized deposits of disease tissue. He was thought to be in the terminal stage of the disease. A course of nitrogen mustard (28 mg.) produced a dramatic fall of temperature and a great improvement in his condition and appetite. He left hospital a week later, but a fortnight after treatment he became very ill and had petechiae, and his haemoglobin was found to be 32%. A transfusion of 1 pint (570 ml.) of packed red cells was given and the level rose over a period of four months to 100%, and by then his general health was excellent. A further course of 25 mg. was given in November because his haemoglobin level had dropped to 86%; after the injections it fell to 60% but recovered spontaneously. Before this course his platelets were 300,000 per c.mm., but by the 15th day they had completely disappeared from the peripheral blood, and he had a few petechiae on his legs, although a capillary fragility test was negative. The pre-treatment level was not regained until eight weeks later. The remission after this course lasted until February, 1948, when a further 25 mg. was given. The haematological changes on this occasion were much less marked. He started getting severe pain in the neck in May, and local deep *x*-ray therapy brought considerable benefit. A further course was given in July; but this had no effect on the fever, which had recurred, and he died in September, 1948.

Platelet counts were not done in all cases, but in a few there was a pronounced fall during the third week after treatment, although purpura was seen in only one case (No. 9).

Nausea occurred in 80% of courses and vomiting in 70%. The latter started, often very suddenly, about three hours after the injection and lasted from two to six hours. It varied greatly in severity, and in three cases was so bad that the last injection of the course was omitted. It was worse after larger doses, but the increase was not marked. Pyridoxin and phenobarbitone were tried but had no significant influence. One patient in the terminal stages of Hodgkin's disease died 48 hours after an injection of 5 mg. She had rather severe vomiting, which probably hastened her death.

Discussion

There can be no doubt that malignant lymphomata, particularly the Hodgkin type, respond to nitrogen mustard therapy. This is shown clinically by regression of lymph nodes, spleen, and other deposits, remission of fever, and

improvement in strength, weight, and blood picture. It is nevertheless evident that this remedy is not curative, and to assess its value the length and completeness of the remissions which follow its use must be compared with those obtained by deep *x*-ray therapy—hitherto the only comparable form of treatment available. It is also necessary to take into account the particular difficulties of the therapy itself. In the case of the nitrogen mustards there are the dangers of the actions on the haematopoietic tissues and the discomforts of those on the gastro-intestinal tract. With deep *x*-ray therapy the duration of treatment is longer, the necessary apparatus must be available, and irradiation sickness and bone-marrow depression may occur.

The course of Hodgkin's disease is extremely variable. It may progress with all degrees of rapidity, and the prognosis cannot be correlated either with the histological appearances or with the clinical picture at any one time. Assessment of any therapy in this condition is therefore difficult, and can be attempted with confidence only on larger series of cases. It is possible to draw only the most tentative conclusions from a series as small as this.

In cases which present with localized glandular masses, nitrogen mustard therapy has not been found satisfactory, because the remissions are much shorter than those following irradiation.

In other cases, however, the disease is more generalized from the onset, with visceral involvement, fever, and anaemia. The *x*-ray bath technique is usually employed in these patients. The present series includes four cases of this type treated initially with nitrogen mustard; two responded well, one moderately, and in one the treatment failed completely. There were neither histological nor clinical features in the last case to explain the disappointing result. The first indication that the condition is responding is a dramatic fall of temperature after the first injection, and absence of such a fall is an ominous sign. The remissions obtained have been of reasonable duration and comparable to those following *x*-ray therapy. Visceral enlargement is a common feature of these cases, and irradiation is often followed by troublesome nausea and prolonged anorexia. With nitrogen mustard the treatment is completed in four days or less, and, although there is a temporary gastric upset, it soon passes and a good appetite develops if the condition is sensitive. It is in this type of case that further trials of nitrogen mustard therapy are particularly required before it can be decided which form of treatment is the more satisfactory.

In the late cases of Hodgkin's disease the problem is more difficult. In those in which there has been repeated recurrence of enlargement of the same group of glands the skin condition may prevent further irradiation and nitrogen mustard should be tried. In terminal cases a dramatic remission is occasionally obtained, and if the case is a chronic one it may be of reasonable duration. In the acute type, however, in which the condition has progressed rapidly, any remission is likely to be disappointingly short. The bone marrow is very susceptible in some of these cases and blood transfusion may be required. The decision to use nitrogen mustard in the terminal stage of the disease should be made only after careful consideration. The chance of an adequate remission is small, although an extra period of useful life may be gained in occasional cases. The patient is liable to have distressing vomiting, which may precipitate a fatal outcome, and severe leucopenia or anaemia is easily produced.

In the management of the typical case of Hodgkin's disease, presenting first with lymphadenopathy and after a slow evolution showing signs of generalization, both irradiation and nitrogen mustard may have their place. The glands should be treated initially with deep *x*-ray therapy, and after the first two or possibly three courses prolonged remissions may be expected. When the intervals get shorter or signs of generalization appear, the patient should be admitted to hospital and a full course of nitrogen mustard given. Complete blood and platelet counts are required at least once a week for four weeks to detect undue sensitivity of the bone marrow. If the response to this course is satisfactory, maintenance injections at four to eight weeks' interval may be used subsequently. These can be given to out-patients at the week-end without interfering with their work, but blood counts must be done before each one. If particularly troublesome local lesions appear at this stage, deep *x*-ray therapy should again be considered.

Summary

A preliminary report is made of the use of nitrogen mustard (the "bis" derivative) in a small series of cases over a period of three years. The dosage and administration of the drug are discussed. Serious haematological complications occurred in some cases, particularly those of advanced disease. Nausea and vomiting and venous thrombosis were troublesome side-effects.

Owing to the difficulty in assessing the degrees of response in such a variable condition as Hodgkin's disease the results have been classified as conspicuous benefit, moderate benefit, and failure. Benefit implies a three-months remission, with return to work in the first case and ability to return home and be about the house in the second.

Cases of Hodgkin's disease presenting with localized glandular masses respond better to radiotherapy than to nitrogen mustard.

Cases in which the disease from the beginning is widespread, involving the viscera, probably do better with nitrogen mustard than with irradiation.

Nitrogen mustard can be profitably used in some of the cases for which radiotherapy is no longer suitable. Surprisingly good results have been obtained at this stage in one or two patients whose disease had run a prolonged course.

I have to thank Professor H. P. Himsworth for guidance throughout this study, the staff of University College Hospital for allowing me to treat patients under their care, Dr. M. Maizels and his assistants for the extensive haematological investigations, and Mrs. E. L. G. Hilton, Director of the Radiotherapy Department at the hospital, who referred many of the patients for treatment and gave much useful advice. The original supply of nitrogen mustard was received through the Medical Research Council.

As an introduction to the social welfare services in Britain the British Council arranged a two-weeks course in London during August for 17 holders of United Nations Social Affairs Fellowships from Argentine, Belgium, China, Egypt, India, and Sweden. The course included lectures by experts illustrated by visits in the London area. These enabled the students to see Queen Mary's Hospital, Roehampton, the Vauxhall Motor Works, Luton, and a housing estate at Bushey, Herts. At the end of the introductory course the fellowship holders followed individual programmes of study, planned by the British Council, on detailed aspects of social welfare such as the treatment and prevention of juvenile delinquency, the rehabilitation of the disabled, welfare among children and young people, and welfare in industry.

TREATMENT OF RINGWORM OF THE SCALP

BY

H. HABER, M.D.Prague

R. T. BRAIN, M.D., F.R.C.P.

AND

J. W. HADGRAFT, Ph.C., A.R.I.C.

(From St. John's Hospital for Diseases of the Skin and the Royal Free Hospital)

The treatment of ringworm of the scalp by the application of preparations containing fungicides in various penetrating vehicles was the subject of an investigation by Brain *et al.* (1948). The best results were obtained with an ointment containing phenylmercuric nitrate 0.5% in a base consisting of "Crill No. 6," which is a non-ionizing surface-active compound, and "carbowax 1500" buffered to *p*H 4–5 by the addition of a solution of citric acid and sodium propionate. This investigation has now been extended to the use of salicylanilide in the same ointment base.

Salicylanilide is a white or pale-cream powder, very sparingly soluble in water, but soluble in alcohol and in the ointment base described above. Its use in the treatment of ringworm infections was first reported in America by Schwartz *et al.* (1946), who used an ointment containing salicylanilide 4.5%, hyamine 1%, and carbowax 1500 94.5%. Hyamine is a quaternary ammonium compound having surface-active properties, and was included to promote penetration of the fungicide into the hair follicle.

More recently the treatment of ringworm of the scalp with salicylanilide has been investigated in Scotland by Kinnear and Rogers (1948). These workers used an ointment containing salicylanilide 4.5%, cetrimide ("cetavlon") 1%, and carbowax 1500 94.5%. It is significant that they also used salicylanilide in a "eucerin" base, and found that it was no more effective than other ointments, whilst the conclusion was reached that salicylanilide in the carbowax base was the only preparation investigated which gave satisfactory results.

The following is the report on 27 cases of ringworm of the scalp treated with an ointment which has the following composition:

Salicylanilide	5 g.
Crill No. 6	10 ml.
Solution of citric acid 2% and sodium propionate 1%	2 ml.
Carbowax 1500	to 100 g.

Melt the carbowax 1500 over a water-bath, add the Crill No. 6, dissolve the salicylanilide in the mixture, add the solution of citric acid and sodium propionate, and allow to cool, stirring occasionally.

Instructions to Parents

The same technique of treatment was employed as in the previous cases. Parents were given written instructions and advised to follow them meticulously. The instructions were as follows:

1. Cut the hair of the entire scalp very short and keep it short throughout the treatment.
2. A linen cap should be worn day and night.
3. Wash the scalp every morning with soap and hot water and scrub the affected parts with a soft nailbrush.
4. Apply the ointment to the lesions with the help of a toothbrush and spread the rest of it into the entire scalp.
5. Report to the hospital should any undue irritation occur.

Remarks on Instructions.—(1) It has been found that whenever the mother failed to cut the hair of the entire scalp infected patches or individual hairs escaped the effect of the treatment. This made a prolongation of treatment necessary. (2) The linen cap prevented the spread of ringworm from infected pillows and hats, and protected the rest of the children in the family from contracting the disease. Several examinations of the inner side of headgears under Wood's light revealed the presence of fluorescing stumps. (3) We still think that mechanical friction is of considerable assistance in the elimination of infected hairs, the epilation being the preliminary step to any effective treatment of ringworm. Our further observations (see below) confirm that. (4) The toothbrush is an additional mechanical factor, and is also a good applicator. (5) Severe reactions such as kerion were not sought, and when these occurred parents were told to report as soon as possible in order to control the inflammation.

Parents were given enough ointment to last two to three weeks, and throughout the treatment the patients were seen only three or four times.

Clinical Picture

Every single case was diagnosed clinically, confirmed by Wood's light and microscopy, and the fungus in question identified by culturing. Both the course of the treatment and the follow-up were controlled with the help of a watchmaker's glass. In the experience of one of us (H. H.) it has proved indispensable in assessing the real progress of each case. It was interesting to watch the behaviour of the infected patches from the first day of the examination to the time of discharge of the case.

Under a watchmaker's glass by daylight an infected patch shows characteristic features which make a clinical diagnosis possible: the infected hair is broken, it has lost its elasticity, and it can be laid in different directions without returning to its previous position. It appears slightly darker, owing to the loss of the hair cuticle.

When looked at under Wood's light with the help of a watchmaker's glass the infected hairs appear brilliantly green, like the fluorescent dial of a wrist-watch, and the hair stumps lie loosely on the scalp but are still fixed in their follicles. When treatment has started, and the case is seen after a period of several weeks, a slightly different picture is presented. The hair stumps are polished off and the infected hairs appear now as brightly shining dots like stars on a dark background, and, when the case is responding, rarefaction of the patch is demonstrable. This rarefaction is due to the fact that a few hairs have already started to fall out, so that when the patch has become negative to Wood's light it does not mean that the affected hair has lost its fluorescence, but that epilation has occurred. As a matter of fact, a cured case shows the patch well polished and smooth, whereas a case which has not responded remains covered with hair stumps, and this fact can always be established by examining the patch with bare fingers. The lesions which have responded are smooth to the touch, whereas those that have not responded feel like a fine grater.

After a few weeks the empty follicles become filled with parakeratotic scales, and when such a patch is examined under Wood's light it seems as if the follicles contain white fluorescent hair stumps, indicating a relapse; but when removed with the help of forceps, placed on a slide with a drop of liquor potassae, and examined under the microscope it proves to consist of dried epidermis cells. Sometimes a few real white hair stumps were removed and proved to contain dry dead spores within them. They were of no significance.

Whenever pustulation or kerion formation occurred (which was accidental), both mechanical and ointment

treatments were stopped at once. A lotion containing acriflavine 1 in 1,000 with 10% tannic acid was applied until the lesions subsided. Crusting and scaling were treated with a sulphur-and-salicylic ointment. Individual infected hairs were dealt with by epilation with forceps.

The usual routine was to examine the patients every two, three, or four weeks. Once the case had become negative the mother was advised to continue with the treatment for another week, after which the treatment was stopped. A monthly follow-up for at least three months was necessary before the cases were discharged as cured, but we tried to extend surveillance as long as possible, and succeeded in a great number of cases in maintaining it up to five, six, or seven months.

Analysis of Cases

The accompanying Table gives a detailed account of the course of treatment of the 27 cases.

Cases of Microsporon felineum.—There were 20 cases in this group. Seven boys and 13 girls. The age ranged between 3 and 11 years. Fifteen cases were cured by salicylanilide alone. The time of treatment was between three and 14 weeks. Three cases, after having been treated with salicylanilide for ten weeks were given carbowax ointment containing phenylmercuric nitrate. They were cured in 7, 8, and 10 weeks. Two cases were epilated by *x* rays. Out of 20 cases, 15 responded and five failed.

Cases of M. audouini.—Six cases, all boys between 4 and 8 years; four were cured—two in six weeks, one in 12, and one in 16. Two cases failed, and were cured by *x*-ray epilation (75% cure, 25% failure).

Case of Trichophyton sulphureum.—A 6-year-old boy proved to be very resistant to local treatment, and after four months had to be referred to the radiotherapist for epilation.

Analysis of Cases

* Sisters. † Brother and sister. ‡ Brothers.
A = *M. audouini*. F = *M. felineum*. T.S. = *Tr. sulphureum*.
Carbo = Carbowax ointment containing 0·5% phenylmercuric nitrate.

Comment

There was local reaction in seven cases, ranging from mild folliculitis and pustulation to true kerion formation. All occurred in *M. felineum* cases, none in the *M. audouini* cases.

Comparison of the results achieved with phenylmercuric nitrate with those achieved with salicylanilide reveals very little difference. It is not the fungicide which effects the cure but the penetrating power of the bases employed. The latter bring about a softening of the hair and a loosening of the connexion between the hair and the hair papilla which effect epilation. Any fungicide will cure when the hair is removed. *X*-ray epilation has to be followed by the application of a fungicide.

We would like to point out that in no case have we seen healthy hairs fall out; the removable hairs were always proved to be infected.

In our previous paper we expressed the opinion that variance of response to treatment might be due to the individual resistance of the fungus to the fungicide. This may indeed be the case, but we would like to add another factor which may be important in influencing response to local treatment: that it is probably the hair itself which resists penetration of the base. From the table it will be seen that three pairs of brothers and sisters failed to respond to local treatment. In our opinion this may have been due to an intrinsic quality in the hair of the same family which was resistant to local forms of therapy.

Summary

A report is given on the treatment of ringworm of the scalp by the application of 5% salicylanilide in carbowax 1500.

Chemical properties of salicylanilide and the literature on its use in the treatment of ringworm are reviewed.

Twenty-seven cases—20 of *M. felineum* infection, six due to *M. audouini*, and one due to *Tr. sulphureum*—were treated.

Cure was effected in 75% of the cases.

No significant differences were observed between the responses to treatment of the human and of the animal type of ringworm.

The results obtained with salicylanilide in carbowax 1500 are practically identical with those achieved with carbowax ointment containing 0.5% phenylmercuric nitrate, as employed in our previous series.

We wish to express our thanks to Imperial Chemical (Pharmaceuticals) Ltd. for the supply of salicylanilide used in these investigations, and to Mr. R. C. Syms, chief technician at St. John's Hospital, for his valuable assistance.

A proposal concerning the formation of a Department of Public Health in the Ministry of the Interior in Western Germany with, ancillary to it, an advisory council and a medical research council to deal with the standardization of drugs, vaccines, and sera is receiving favourable consideration by the German authorities, according to the July report of the Control Commission for Germany (British Element). As a result of a meeting in Geneva on June 1, 1949, at which a British and a German representative from Nordrhein-Westfalen were present, the World Health Organization has set up an International anti-Venereal-Disease Commission of the Rhine. This commission, consisting of experts on venereal disease from France, Holland, Belgium, Switzerland, and Germany—from the countries bordering the Rhine—with representatives of the Occupation Authorities of the Western Zones, made a technical study tour of the main venereal-disease treatment centres in the Rhine River area. This was the first step towards the co-ordination of the anti-venereal-disease services in the five countries concerned.

ASPIRIN POISONING

BY

IVAN LEVESON, M.D., D.P.M.

Clinical Assistant, Psychiatric Department, Royal Southern Hospital, Liverpool

Reports of cases of aspirin poisoning, with the exception of those of Balázs (1930, 1931), have in the main been concerned with isolated instances and have discussed the clinical features, the difficulties of diagnosis, the post-mortem appearances, or therapeutic measures (Dyke, 1935; Wyllie, 1935; Neale, 1936; Charters, 1944). Hopkins (1945) was able to collect only 22 cases from the English literature during the years 1919–45, when he reported a case with recovery after the ingestion of 1,250 gr. (81 g.).

In the present paper the clinical features of aspirin poisoning are described from experience of 48 cases of attempted suicide with aspirin seen in the past two years. Two were fatal. These patients were all seen in the psychiatric wards of a general hospital serving, for purposes of Section 20 of the Lunacy Act, an urban population of about a million inhabitants. All cases of attempted suicide in the area notified to the police or to relieving officers before the National Health Act and to duly authorized officers since are brought to these wards, and therefore an unusual opportunity exists for observing a high percentage of the cases of attempted suicide in a large population.

From the figures presented in Tables I and II it is apparent that there has been a relative and an absolute increase in the number of cases of aspirin poisoning with

TABLE I.—*Incidence of Aspirin Poisoning: Males*

	1940	1941	1942	1943	1944	1945	1946	1947	1948

suicidal intent in 1947 and 1948 in this area. During this period there were 48 cases of aspirin poisoning out of 284 cases of attempted suicide. The increase is mainly confined to females. Aspirin is the household remedy in most common use, and this ready availability is no doubt the most important factor in the increased incidence. Several other interesting points emerge from an examination of these tables. In males there was a higher attempted suicide rate over the period 1945 and onwards, whereas in females this increase did not occur until 1947. Before 1947 aspirin was used in about 10% of attempts at suicide in females, while over the past two years this figure has increased to between 20 and 25%. It has often been observed that attempts at suicide are relatively infrequent during the first quarter of the year. Table III illustrates not only this but also that, remarkably, no cases of aspirin poisoning occurred during this period of 1947 or 1948.

TABLE III.—*Quarterly Incidence of Attempted Suicide: Females*

Totals ..	438	67	16	450	95	21

In the description that follows no special attempt is made to classify the cases according to the psychiatric manifestations. Hopkins (1937) described psychotic patients adopting self-mutilation, cut throat, hanging, immersion, and the caustic poisons for purposes of attempting suicide. The more bizarre the attempt the more questionable is the mental state. In my series of cases the psychic manifestations were in the main relatively mild.

No minimum fatal dose has been established, although most of the recorded deaths occurred within the range of 400–600 gr. (25.9–38.9 g.), but recovery has taken place after very much larger amounts. Hopkins (1945) reported 1,250 gr. (81 g.) (treated within three hours); Evans (1938) 1,500 gr. (97.2 g.) (treated within two hours); and in one of my cases 2,000 gr. (129.6 g.) (treated within five hours). In these three cases gastric lavage was performed early and powder was found in the stomach washings. In contrast to these cases, which recovered after early recognition and treatment, Biddle (1938) reported a fatal case with epileptic convulsions preceding death, which took place after 17 hours. The patient was a schizophrenic with delusions, and her story of having taken the aspirins was not believed.

Clinical Features

These are determined by two factors—excessive dosage and individual susceptibility. The earliest symptoms are mainly gastric and occur shortly after taking the drug. There is first a feeling of gastric discomfort, followed by pain in the epigastrium, nausea, and later vomiting. These symptoms are doubtless due to the direct irritant effect of the aspirin on the gastric mucosa (Douthwaite and Lintott, 1938). Aspirin is relatively insoluble, and large fragments will remain in contact with the gastric mucosa for a long time. The presence of an irritant in the stomach often leads to some degree of pylorospasm, which will delay the passage of the aspirin. This explains the finding of aspirin powder in the stomach after the normal emptying-time, and the value of gastric lavage up to many hours after the ingestion of the tablets.

Giddiness, tinnitus, and deafness occur later, and in the average case last for as long as 48–72 hours. The face often shows a blotchy erythema with some oedema, especially around the eyes. Profuse perspiration has been a constant finding. The patient is literally bathed in sweat until the toxaemia is overcome, and is very restless and resentful of interference. In Hopkins's (1945) case hallucinations occurred over a period of four days, but I have not met with this symptom. In more severe cases coma supervenes and the patient shows the features of shock, with subnormal temperature and low blood pressure. Renal symptoms have not played a prominent part in my cases, and I observed no abnormality apart from the presence of traces of albumin in the urine. Other authors have found greater evidence of renal damage. The speed with which treatment is usually possible may have some bearing on this finding. Haematemesis was not observed in my series. A pyrexia of up to 100 or 101° F. (37.8 or 38.3° C.) was often seen during the first 48 hours in severe cases.

Many of the clinical features are the result of acidosis with reduction of the alkali reserve. Respirations are deep

and rapid, but in spite of the apparent urgency of the respiratory embarrassment there seems to be little discomfort, and in no case has the patient complained of it. Severe or acute allergic reactions were not seen. The only findings suggestive of allergy were the slight oedema around the eyes and the blotchy erythema of the face. Dehydration, which develops if an adequate intake of fluids is not assured, is the result of the profuse perspiration and the rapid deep respirations.

Diagnosis and Prognosis

Diagnosis may be a difficult problem, especially where no history is available, and patients who have taken poison with suicidal intent may on occasion withhold this information even when conscious. One patient denied that she had taken any drug even after she had vomited material with the appearance of aspirin and giving the chemical reactions of acetylsalicylic acid. Aspirin poisoning should be considered when there is a blotchy erythema of the face with profuse perspiration and tachypnoea and tachycardia without distress, cyanosis of severe degree, and pathological signs in the heart or lungs.

Examination of the urine is a particularly valuable diagnostic measure. Aspirin is excreted in the urine as salicylic acid, which gives a purple colour with ferric chloride. To about 5 ml. of urine 10% ferric chloride is added drop by drop. A white precipitate of ferric phosphate is obtained and the urine then turns purple if salicylates are present. To distinguish this coloration from that produced by the presence of aceto-acetic acid, boil thoroughly 10 ml. of the urine, cool, and add ferric chloride. If the urine contains salicylates it will still give a purple colour; if it contains aceto-acetic acid there will be no colour change; and if it contains both substances the purple colour will be less intense than before (Harrison, 1947). Confirmatory tests are also described by that author.

In mild cases recovery is rapid, symptoms clearing in the first 48 hours. In the more severe cases coma may supervene and death may occur at any time during the first 72 hours. This is usually preceded by a rise in temperature; epileptic convulsions have been described, and stertorous or gasping respirations occur more regularly, with myoclonic twitching of the face and limbs. During 1947–8 there were two deaths out of the 48 patients seen. The first was the result of bronchopneumonia even though treatment was instituted early and the patient had been in good condition when first seen; in the second the patient was moribund on admission to hospital, having taken the aspirin almost three days previously.

During the period 1940–8 there were seven deaths associated with aspirin poisoning. Obvious pathological symptoms were present in two of these and the aspirin was only contributory. In the first there was a large cerebral haemorrhage, and in the second advanced generalized atherosclerosis with hypertrophy of the left ventricle and renal changes. Most of these seven patients had taken 500 gr. (32.4 g.) of aspirin, one dying after 400 gr. (25.9 g.) and another after 625 gr. (40.5 g.). In none of the seven cases had the patient been brought to hospital within the first twelve hours—i.e., during the period that gastric lavage would be of value. The majority were not seen until after the first 24 hours, and in two cases there was a lapse of at least 48 hours. The patients were either comatose on admission or rapidly became so after admission, and death occurred within five hours in three of the cases. The treatment in these cases included the use of stimulants (nikethamide, strychnine, etc.), drainage of C.S.F., intravenous fluids, and sodium bicarbonate. From the records available these measures do not seem to have greatly modified the clinical picture before death.

Briefly, the post-mortem findings have been those of an asphyxial death: cyanosis of the skin and viscera, petechial haemorrhages on serous surfaces, and congestion of the lungs. In one case bronchopneumonia developed on chronic bronchitis, and two others showed gross morbidity as indicated above.

Treatment

In general, early gastric lavage is the most important single therapeutic factor. All the measures advocated by Dyke (1935), Neale (1936), Oakley and Donnell (1942), and Charters (1944) have their place, depending on the clinical picture and the general condition of the patient. Although the degree of toxaemia inevitably depends on the amount of aspirin taken, subsequent clinical events bear a more direct relation to the speed with which treatment is instituted. If gastric lavage can be performed within the first few hours of taking the drug recovery can almost be assured. In the case described below 2,000 gr. of aspirin had been taken, yet the patient recovered, although she was dangerously ill for about 36 hours before improvement was apparent. In this connexion it is noted that all the deaths occurred in patients whose admission to hospital had been considerably delayed. Where this delay occurred treatment had no apparent effect on the patient's condition.

The bulk of the patients were brought to hospital within a few hours of taking the drug. Where the diagnosis was clear from the history—and a history was usually available—immediate gastric lavage was performed. A clinical impression is that washing the stomach with a weak solution of sodium bicarbonate is a better measure than using simple water. The stomach is washed until no trace of aspirin powder can be seen in the washings, and then, before the tube is withdrawn, one pint (570 ml.) of a solution containing 1% sodium bicarbonate is left in.

Later sodium bicarbonate is given in doses of 60 gr. (3.9 g.) at two-hourly intervals for a time and then four-hourly, depending on the clinical picture. If there is evidence of increasing acidosis two-hourly doses should be given, but as soon as acidosis is being overcome four-hourly doses are sufficient. In all but the deeply comatose—and this is a rare event if treatment is started early—the sodium bicarbonate can be given by mouth in water, soda-water, or milk. Fluids should be pushed to prevent dehydration. Shock is treated by the usual simple methods of warmth and intravenous fluids, the latter especially if there is any dehydration. Where there is evidence of vasomotor collapse with a pronounced fall in blood pressure "eucortone" or desoxycortone acetate is valuable.

The patient is made more comfortable with sponging, but care should be taken to prevent pulmonary infection, and penicillin should be given prophylactically until acidosis has been controlled. Where treatment as described above was adequately and speedily carried out, especially the gastric lavage, improvement was rapid, and within 48 hours the condition of the patient was good and such symptoms as tinnitus, deafness, tachypnoea, and excessive perspiration to all intents disappeared. It is doubtful whether intravenous sodium bicarbonate can influence severe and late cases. Lumbar puncture was used in such cases but only with other medication, and it is again doubtful whether the result was modified by this measure. A practical difficulty in carrying out lumbar puncture may be the

The other three patients could have been saved only by earlier transfusion or by surgery.

The age distribution, given in Table I, confirms the increasing incidence of this disease among older patients already shown in other recent series. This has an important bearing on the death rate. One would expect better results in a series with an unduly high proportion of young patients in it.

Thirty-three ulcer cases were treated surgically: 16 as soon as they could be prepared by transfusion, 13 because they had a second brisk haemorrhage, and four because prolonged medical treatment failed to control their haemorrhage. The ages of these four were 23, 24, 31, and 36. They were operated on because it was considered that nothing else would save them. The case history below is given as an example of unduly severe haemorrhages in a young man.

Case 15. Chronic Duodenal Ulcer.—This patient was an extremely fat man of 24 who had had attacks of dyspepsia at six-monthly intervals for five years. Just before his admission he vomited "two pints (1 litre) of blood." He looked very fit and his Hb was 80, but his pulse was 116. At the end of a 2-litre drip transfusion his pulse was 130 and he had vomited a great deal of blood and had had several melaena stools. Forty-eight hours after admission he had received by drip 6 litres of blood. His pulse was now 140. It was quite obvious that a vessel was bleeding faster than he could be transfused, and must be stopped. At operation I accidentally knocked the clot off the gastro-duodenal artery and started a haemorrhage which reminded me of a slipped renal pedicle. The torrent was soon stopped with two stitches, and a high gastrectomy was completed at leisure without his condition deteriorating further. The 3 litres of blood used in the theatre and afterwards brought the total to 9 litres.

The Chronic Gastric Ulcer Group

Of the 39 cases in this group 23 were treated medically either because they were not considered fit for surgery or because the haemorrhage was not dangerously severe. Of these medical cases eight subsequently required gastrectomy. The 16 surgical cases were all treated by gastrectomy, the operation being technically easy in most of them and the ulcer usually easy to find. The bleeding vessel in all cases but two was a branch of the left gastric artery eroded in the subserous fat on the lesser curvature. The surgical deaths both occurred in this group. In neither case was death attributable to the fact that the operation had been performed in the presence of haemorrhage.

G.D.A. = Gastro-duodenal artery. R. = Recovered.

The Chronic Duodenal Ulcer Group

There were 41 patients in this group and eight were treated surgically. They all recovered after partial gastrectomy. Three of them were desperately severe cases whose recovery under medical treatment would have been very unlikely.

Case 30.—This patient, a man aged 67, did not start to bleed until the day of his admission, and when he arrived he was so collapsed that it was doubtful whether he would survive long enough to be transfused. No pulse was palpable and no blood pressure could be recorded. Four hours later he was fit enough for the theatre. Operation revealed the gastro-duodenal artery lying exposed in a duodenal ulcer crater in the pancreas. It was underrun and a gastrectomy was performed. He was very ill for some days owing to leakage from his stump, but soon made a rapid recovery. He received 6 litres of blood, most of which was required to replace what he had lost during the short time he was bleeding.

8	40 M	3 "	Many	1½	" "	Had bled previously	"

R. = Recovered.

The Acute Ulcer Group

This common lesion of the stomach or duodenum was the cause of approximately one-third of the haemorrhages admitted to hospital. The diagnosis is not always correct, being based largely on negative evidence and subsequently confirmed in most cases by a negative radiograph. It is a lesion probably rapid in its development and similarly rapid in its healing. The vessels by which it bleeds are the arteries of the submucosa. Most of these vessels are small, and the involvement of a large vessel is probably a chance affair determined by the accident of the site of the ulcer.

TABLE V.—*Operations for Haemorrhage Following Gastro-jejunostomy or Gastrectomy*

Case No.	Age and Sex	Date and Nature of Operation	Ulcer	Blood (litres)	Treatment (Same Day)	Result
13	49 M	1924, Gastro-jejunostomy	Small Chr. G.U.	1	Gastrectomy	R.
14	42 M	1946, Gastrectomy	Large Chr. G.J.U.	3	2nd Gastrectomy	"
12	66 M	1916, Gastro-jejunostomy	Large Chr. G.U.	½	Gastrectomy	"
11	63 M	1924, " "	Acute G.J. ulcers	2	G.J. undone	"

R. = Recovered.

As these ulcers respond so well to medical treatment, and as they would never require surgery if they did not bleed, operation should be undertaken only in order to save life or because a chronic ulcer is suspected. If they are operated upon, local excision would be the best procedure if one could be sure that there was only one ulcer and if it is likely to be technically easy. All the 48 patients in this group recovered. There were five surgical cases, four of them being treated by gastrectomy.

Gastro-jejunal Ulcers

The diagnosis of gastro-jejunal ulcer was made clinically in patients who had had a previous operation—either a short-circuit or a gastrectomy. This diagnosis was sometimes wrong, but it is used as a convenient one for this group, which presents a special problem for the surgeon, who has to weigh the fact that a chronic ulcer is almost certainly present and demanding surgery against the added difficulties and dangers of a complicated resection. Of the seven patients in this group three bled from the original gastric or duodenal ulcer for which the short-circuit had been performed and one from an acute jejunal ulcer. The recovery of the four surgical cases was largely due to early operation. They were all operated on very soon after admission.

Case 14.—This patient, a man aged 42, was known to have a large gastro-jejunal ulcer which had followed an inadequate gastrectomy for duodenal ulcer. He was extremely collapsed and actively bleeding when he was admitted. To make him fit for operation 2½ litres of blood were required. Exploration revealed an enormous gastro-jejunal ulcer which penetrated deeply into the pancreas. In the base of the ulcer was a large artery with a fresh thrombus in it. A further 2 in. (5 cm.) of stomach was resected, and a fresh anastomosis was formed. A year later he underwent his third gastrectomy (and vagotomy) for another ulcer, which this time eroded deeply into the liver.

Other Cases.—Two patients not included in the series were treated surgically. One had a large carcinoma and recovered well after a total gastrectomy. The other patient bled profusely a week after the suture of a perforated gastric ulcer. He died after a long, tedious resection.

Summary and Comment

For several years all patients suffering from haematemesis or melaena admitted to the Royal Berkshire Hospital have been treated in the surgical wards. In the last three years 135 patients with peptic ulcer haemorrhage have been so treated, with a mortality of 7.4%. Under the age of 40 there were no deaths, no women died, and no patient died from an acute ulcer. Thirty-three patients were treated by operation, with two deaths. Although some patients were treated medically and some by surgery the principle of treatment was the same in all cases, and no comparisons can or should be made between the medical and the surgical results. This principle was that each patient was considered as a potential surgical case and was operated upon as soon as his life appeared to be endangered by his complaint. If surgery is to be used in this way it is justifiable only if a low surgical mortality can be achieved. A low mortality is dependent on careful judgment in the selection of cases, adequate and efficient transfusion, and early operation.

It was in consultation with Dr. John Mills, director of the pathological department, that most of these patients were treated, and I would like to express my gratitude to him both for this help and for the efficient transfusion service that he maintains. I am also grateful to my colleagues, who allowed me to treat these patients in my wards.

IONTOPHORESIS IN THE TREATMENT OF PERIPHERAL VASCULAR DISEASE

BY

H. S. PEMBERTON, M.B., F.R.C.P.

AND

D. C. WATSON, M.C., M.B., M.R.C.P.

(From the Medical Unit, David Lewis Northern Hospital, Liverpool)

Among the methods of treatment designed to overcome vasospasm or to produce vasodilatation in peripheral vascular disease the use of choline derivatives is suggested by the work of Dale and Gaddum (1930) and Dale, Feldberg, and Vogt (1936). Acetylcholine is unstable and rapidly hydrolysed in the tissues (Renshaw *et al.*, 1938). Its action on the autonomic nervous system is a double one, producing both muscarine- and nicotine-like effects. Some of its esters do not share these defects, and in this study we have been able, using the method of ion transfer, to compare the actions of the anions of two substances: acetyl-β-methylcholine ("mecholyl" and "amechol") and carbaminoylcholine ("carbachol," "doryl," and "moryl").

Pharmacology

The action of carbaminoylcholine, the official name of which is carbachol, resembles that of acetylcholine, but is more prolonged. The Simonarts (1934) showed that its nicotine-like action was stronger than in the case of acetylcholine. Fraser (1938) pointed out that its action on the cardiovascular system passes off in 30–40 minutes, though its effect on the gastro-intestinal tract and urinary bladder may persist for several hours.

Acetyl-β-methylcholine also has a relatively prolonged action, and Simonart (1932) showed that the methyl-group substitution deprived acetylcholine of its nicotine-like action. Its effects, in contrast to those of carbachol, are most pronounced on the cardiovascular system.

The method of ion transfer has been shown by Kovacs (1934), Saylor, Kovacs, *et al.* (1936), and Kramer (1937) to be superior in peripheral vascular disease to oral, subcutaneous, and intramuscular administration of compounds of this type. Montgomery, Holling, and Friedland (1938) determined by direct (plethysmographic) measurement the increased blood flow produced in the limbs of normal subjects by mecholyl iontophoresis, and their results fully confirmed the belief that this treatment effected dilatation of blood vessels specifically in the treated part. It is a further advantage that such unwanted general effects as micturition, defaecation, salivation, and bronchial spasm are much diminished when parasympathetic stimulants are given iontophoretically.

Method

The technique of Kovacs, Saylor, and Wright (1936) has been employed throughout. Reinforced asbestos paper is saturated with a 0.5% solution of the substance to be used and wrapped round the leg or thigh. A malleable metal plate, connected to a positive galvanic pole, is placed over this and held in position with a rubber bandage. A large flat electrode moistened with normal saline is placed under the back and connected to the negative pole. The electrodes should not be applied over any raw or inflamed areas or over recent scar tissue. The skin should always be protected by the asbestos paper from direct contact with the metal electrodes, so that burns may be avoided.

The current is turned on gradually at the beginning of each treatment and reduced slowly to zero at the end. A current of 5 mA passing for five minutes is used at the first session, these figures being gradually increased on subsequent occasions, but 30 minutes' treatment at 30 mA is not usually exceeded at any one time. The most useful warning of overdosage is the patient's reaction. Any more than a slight redness or sweating of the part treated is an indication for stopping treatment.

No rigid rules can be made for frequency of treatments, though thrice weekly was most usual in our cases. Duration of therapy is determined by the patient's response; but where treatment has been given over a period of three to four weeks without benefit the method is unlikely to be of value.

Severe general parasympathetic effects may conveniently be dealt with by an injection of 1/100 gr. (0.65 mg.) of atropine sulphate. Bronchial asthma, hyperthyroidism, and recent cardiac infarction are all contraindications to iontophoresis with these substances.

intervention was necessary. Satisfactory or partial improvement was seen in 56 cases (67%). A general survey of the table shows clearly that better results were obtained by the use of acetyl-β-methylcholine (Groups I and III) than with carbachol (Group II). The eight cases of senile gangrene were relatively resistant to iontophoresis with either compound, and similarly disappointing results were found in Raynaud's and Buerger's diseases and in acrocyanosis, but the number of cases was too small to allow any conclusions to be drawn. It is likely that some of these cases were more suitable for sympathectomy. We were unable to confirm the good results of Murphy (1937) in the treatment of thrombophlebitis by this means, and have latterly abandoned it.

The most satisfactory results were seen in 24 cases of intermittent claudication and 21 cases of diabetic gangrene. Improvement was observed in 19 cases of the former (79%) and in 16 cases of the latter (76%).

From our results we cannot infer, as did Kramer (1937), that iontophoresis with parasympathetic stimulants pro-

Condition	Group I (1938–41)				Group II (1941–6)				Group III (1946–8)				Totals

Totals	30	11	11	8	27	4	11	12	26	10	9	7	83

Results

Numerous workers, particularly in America, have obtained good results in peripheral vascular lesions. Kramer (1937), using mecholyl iontophoresis in 30 cases of various types, observed beneficial results in 22. Murphy (1937) treated 33 cases of thrombophlebitis by the same means, and found substantial improvement in 31. Ready healing of associated varicose ulcers was seen. Saylor, Kovacs, *et al.* (1936) obtained satisfactory results in 23 out of 26 patients with varicose ulcers.

The present series, comprising 83 unselected cases, covers the period from 1938 to 1948. The cases are divided into three almost equal groups by the exigencies of the recent war. Having used mecholyl from 1938, we were deprived of it in 1941 and used doryl, moryl, and carbachol as substitutes. It was not until 1946 that acetyl-β-methylcholine again became available as amechol.

The standard adjuvant treatment given to these patients consisted of rest, warmth, and antiseptic measures where necessary; in cases of diabetes mellitus the blood-sugar level was kept within reasonable limits. The patients were usually in bed, though the majority of cases of intermittent claudication were treated as out-patients. The results obtained are detailed in the accompanying table.

Discussion

The method of treatment described cannot be regarded as an isolated piece of therapy, nor is a cure claimed in any case. The pathological basis of most of these conditions is patently irreversible.

Improvement was judged to be satisfactory when either all symptoms disappeared or only minimal local surgical duces its best results in vasospastic cases. The great majority of our cases of intermittent claudication and diabetic gangrene showed mural calcification of the vessels radiologically, and we feel that this finding should not be regarded, as it often is, as a contraindication to the iontophoretic use of such compounds. It is our firm belief that this method is applicable, in the first instance, to all cases of peripheral vascular disease. Our aim has been, by perseverance with the treatment, to avoid the need for surgery or to reduce to a minimum such operative measures as may eventually prove necessary.

Summary

The treatment of 83 cases of peripheral vascular disease by iontophoresis is described. The greater value of acetyl-β-methylcholine for this purpose is shown.

This work could not have been undertaken without the unfailing help of Miss A. M. Clark and Miss A. Fazakerley, successive heads of the department of physiotherapy at the David Lewis Northern Hospital.

Medical Memoranda

A Case of Cutaneous Horn of the Arm

Cutaneous horns of varying sizes are described in the literature. The largest that I have found recorded is the case of Dr. Herman Carache, mentioned in Sutton and Sutton's *Introduction to Dermatology*. This was a scalp horn 8 in. (20 cm.) long, complete, but with a small base. The interest of the following case lies in the large size of the horn, together with its history and the unusual site from which it grew.

CASE REPORT

The patient, a man aged 53, sustained burns of the whole extent of the dorsum of the left upper arm and parts of the leg and back by a German flame-thrower in the 1914–18 war. The greatest loss of tissue was from the arm area, which was skin-grafted (heterogeneous Thiersch) from a nursing sister's thigh. He was in hospital for 18 months.

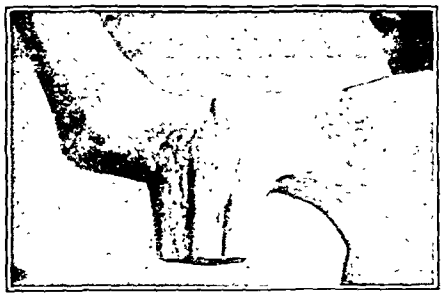

FIG. 1.—Showing extent and attachment of the horn.

The graft remained healed for twenty years, until 1938, when a minor injury to the arm broke the skin. This healed with simple treatment, but after a few months a tumour began to form at the site of this latter skin lesion. At first it was small—"the size of a hazel-nut"—but it steadily grew in base area and length. The direction of the growth was downwards in a curved manner. The tumour was painless, and when it became embarrassingly large the patient or his wife periodically cut off a piece with a hacksaw. Last year the medial side of the base became painful and forced the patient to seek medical advice.

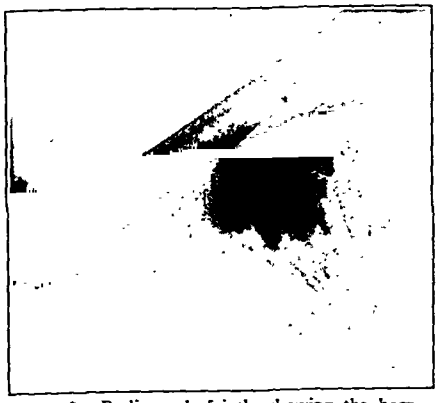

FIG. 2.—Radiograph faintly showing the horn.

On presenting himself at the out-patient department of this hospital the clinical findings were as follows: A large hard horny mass (Fig. 1) growing from a scarred area at the back of the left upper arm, tapering from an oval base; greasy surface longitudinally ridged; yellowish buff in colour; circumference of base 13 in. (32.5 cm.), length of horn 5½ in. (13.75 cm.), but it had been pared down. The cut surface had areas of dark discoloration and was similar in appearance to a sponge. The medial side of the junction of horn and skin was inflamed and tender and had signs of new extensions of the horn. The growth was movable over the deep structures of the arm. Skin-scarring extended in the posterior axillary fold and back of shoulder and elbow. Shoulder abduction was limited to 90 degrees; other movements were full. No axillary glands were felt. The patient brought with him a small bag containing the pieces he had sawn off. These numbered 17 and were of various sizes and similar in appearance and consistency to the main mass. A radiograph (Fig. 2) faintly showed the horn.

The growth was removed by Mr. N. Ross Smith and a skin flap was fashioned from the chest wall, which has healed well by first intention. At operation the base was found to be quite smooth and there was no infiltration.

The specimen has been accepted by the Museum of the Royal College of Surgeons, where the horn was patiently reconstructed from the main mass and the fragments (Fig. 3), showing what it might have looked like had it not been pared down by the patient.

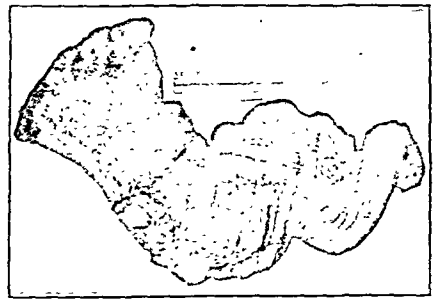

FIG. 3.—The reconstructed horn.

I am greatly indebted to Mr. N. Ross Smith, under whose care the patient was admitted, for help and advice and permission to publish this case. My thanks are due to Mr. L. S. Allison for the first photograph, to the Curator of the Royal College of Surgeons Museum for the photograph of the reconstructed horn, to Miss M. Gall for the radiograph, and also to the patient for his helpful co-operation.

V. R. TADROS, M.R.C.S., L.R.C.P.,
Casualty Officer, Royal Victoria and West Hants Hospital, Bournemouth.

Calcified Cyst of the Spleen

In the *British Medical Journal* of December 25, 1948 (p. 1106), Donovan described a case of calcified cyst of the spleen and stressed the rarity of the condition. It therefore seems worth while to record the following case.

CASE REPORT

The patient was a man aged 62 with no significant past history. He stated that for the last 12–15 months he had had a feeling of lassitude and gradually deepening depression. This was the feature of his illness which most affected him. His appetite was very poor and he thought he had lost several stones in weight in the past few months.

On examination he was seen to be grossly anaemic (haemoglobin 5.8 g. per 100 ml., red cells 4,100,000). In the right iliac fossa and hypogastrium a rather vaguely outlined fixed mass was palpable. No glandular enlargement could be made out. On deep inspiration the tip of his spleen could just be felt. It was firm in consistency. Radiologically the result of a barium enema was rather indefinite, but suggested a

neoplasm of the caecum. Owing to his general condition surgical intervention was considered to be inadvisable for the time being, but before there was sufficient improvement to warrant it he collapsed suddenly and died.

At necropsy, on opening the abdominal cavity a great quantity of serous fluid was found. A large solid tumour involving the caecum and invading the surrounding structures was also seen. There was a small recent perforation through the growth, shut off by adhesions from the rest of the peritoneal cavity. The tumour was immobile and quite inoperable. Histological sections proved it to be an adenocarcinoma.

The spleen contained, at its lower pole, a single cyst 4 cm. in diameter, with a calcified wall so hard that it necessitated bisection with a saw. It contained a few millilitres of rather iridescent yellowish fluid and many cholesterol crystals. The lower quarter of the cyst wall did not appear to be covered by the splenic capsule, nor was it adherent to adjoining structures. Histological section of the wall showed it to consist of hyaline and acellular fibrous tissue in an advanced state of calcification. There were no apparent changes in the spleen either adjacent to or remote from the cyst.

Other features noted at the necropsy were a moderate degree of atheroma of the aorta, arteriosclerotic kidneys, a cirrhotic liver, and bilateral bronchopneumonia. There was oedema of the meninges and subcutaneous tissue. Both pleural cavities and the pericardial sac contained serous fluid.

COMMENT

As in the case described by Donovan, no history of trauma was obtained. The splenic artery was not involved. The condition of the spleen, although it was just palpable, was discovered only at necropsy and seemed to have no bearing on the patient's illness.

No scolices or hooklets were found in the cyst fluid, nor was there an eosinophilia in the blood. Serological and sensitivity tests for hydatid disease were not carried out, as the condition was not suspected before death. The finding of cholesterol crystals suggests that the cyst was in fact an old haematoma, although no haematoidin crystals or other blood elements were seen.

K. E. A. HUGHES, M.R.C.S., L.R.C.P.,
Pathologist, St. John's Hospital, Lewisham.

Volvulus of the Entire Small Intestine

Torsion of the mesentery of the whole small intestine is uncommon. I have been able to find accounts of only 61 cases in the literature.

CASE HISTORY

A male Bedouin Arab aged 35 complained that 14 hours reviously he had suddenly been stricken with severe central abdominal colic which was followed by frequent vomiting at first of food and later of bile. The bowels had not been opened.

On examination he appeared dehydrated. Small quantities of bile-stained mucus were being vomited. The abdomen was distended and diffusely tender. Peristaltic sounds were absent. The hernial orifices were normal and rectal examination was negative.

I performed laparotomy at once (September 17, 1942) under open ether anaesthesia. Dark-red congested loops of small intestine appeared to fill the abdomen. The caecum was collapsed and much raised in position, but an empty loop of small intestine could not be found. The entire small intestine was therefore delivered without the incision. It could then be seen that there was a torsion of the whole mesentery, which arose from a deep trough of peritoneum, most striking in appearance. A deep vertical fold of peritoneum had been pulled up by the raised caecum from the right iliac vessels, while another deep ridge had been drawn down from the duodeno-jejunal flexure on the left side. The intestine was rotated counter-clockwise through three-quarters of a circle, thus restoring the normal axis of the mesentery, which was seen to be abnormally long. The gut was viable, so it was replaced and the abdomen was closed in layers. Saline was given subcutaneously and per rectum. Convalescence was uneventful.

DISCUSSION

The predisposing cause of volvulus is an abnormally long mesentery with a narrow base (Burgess, 1902; Dott, 1923). Volvulus is not rare in the newborn, especially in infants who already have a malrotation deformity of the intestine (Fletcher, 1922; Dott, 1927; Metzger, 1939; Voss, 1939; Thompson, 1940; Pouyanne, 1941). In adults, however, even if there is a congenitally long mesentery, some exceptional circumstance must initiate the twist. This is most often the ingestion of a large meal of coarse food on an empty stomach (Pupini, 1932; McKechnie and Priestley, 1936; Kerr and Kirkaldy-Willis, 1946). Shortly before the onset of symptoms my patient had consumed an enormous meal of mutton, rice, and unleavened bread after fasting from dawn till dusk, for he was a Moslem and the season was the feast of Ramadan. In Russia volvulus is commoner in times of famine (McClure, 1935). The activating mechanism may well be that a sudden body movement or strain causes a loaded loop of jejunum to descend by gravity, displacing lighter empty loops. This would accord with the fact that the direction of volvulus is clockwise in 75% of the recorded cases in which it is mentioned.

In diagnosis, repeated vomiting of small quantities of bile-stained material is stressed by Burgess (1902), Garrow (1917), Charsley and Richardson (1928), McClure (1935), Stalker (1939), Thompson (1940), and Barbosa (1944). Some of these authors state that faecal vomiting does not occur even late in this condition. In addition, the abdomen rapidly becomes silent to auscultation. The very quantity of distended congested small intestine is perplexing when the abdomen is opened at operation. Vaughan (1903) and Barbosa (1944) stress the difficulty of recognizing the condition at all, and point out that in at least four of the reported cases the surgeon was unable to discover the cause of the obstruction and closed the abdomen without remedying it. Diagnosis was made at necropsy.

Routier and Delbet (quoted by Vaughan, 1903) separately observed a peritoneal fold running upwards from the right iliac vessels similar to that which I have described. It therefore seems that without complete evisceration of the small bowel the diagnosis cannot be made or derotation be accomplished.

Reviews

THE SURGICAL PATIENT

Care of the Surgical Patient. By Jacob Fine, M.D. (Pp. 544; illustrated. £2.) Philadelphia and London: W. B. Saunders Company. 1949.

This is not a textbook of surgery but a practical guide to the management of the surgical patient. It represents the practice of the Beth Israel Hospital in Boston. Associated with the editor are 22 of his colleagues, each of whom is responsible for a separate part.

The book is made up of six sections. Part 1, "General Considerations," includes such subjects as fluid balance, shock, and infections. Part 2, "Regional and Special Surgery," discusses abdominal, neurosurgical, orthopaedic, plastic, and dental surgery. Part 3 is on endocrine and hormone therapy. Part 4 on coincidental medical illnesses in surgical patients. Part 5 gives an account of clinical and laboratory methods, and Part 6 describes pre-operative and post-operative care. This last section contains articles on anaesthesia and the treatment of acute poisoning.

To the English reader certain terms require to be defined. What, for example, is a Zimmer collar (p. 79)? Or a Barton bandage (p. 106)? Or a Koenig-Rutzen bag (p. 155)? Illustrations would be helpful. Is it true to say that sooner or later the Brown-Séquard syndrome appears in cases of tumour of the spine or spinal cord? Except occasionally in the cervical region, this syndrome is rare in cases of cord tumour and is not often found on clinical examination. Frontal craniotomy is favoured for pituitary tumours; but the curious qualification is made that, "in case the field defect indicates congenitally short optic nerves, the transphenoidal approach is preferable" (p. 72). This requires explanation, as the transphenoidal approach has been so widely abandoned. Again, illustrations would be of value.

There are not many pictures in the text, and these have in many cases been borrowed from Hamilton Bailey, de Quervain, or others, and unfortunately lack text references. Objection is likely to be taken to the misleading association of Sir Gordon Gordon-Taylor's name with the statement (footnote, p. 116) that simple mastectomy combined with post-operative radiation gives the highest cure rate obtainable in cases of cancer of the breast. Most surgeons in this country still prefer to remove lymphatic nodes rather than irradiate them.

The field covered by this book is a large one; it is well ploughed in certain parts, but in others the surface is merely scratched. Its chief appeal will probably be to the students of the Beth Israel Hospital, whose teachers have provided them with a valuable guide-book and companion for their use in the surgical wards.

LAMBERT ROGERS.

NURSING IN NEUROSURGERY

Nursing Care of Neurosurgical Patients. By Roland M. Klemme, M.D., F.I.C.S., F.A.C.S. (Pp. 117; illustrated. 15s.) Springfield, Illinois: Charles C. Thomas. Oxford: Blackwell Scientific Publications. 1949.

The number of new specialties in surgery, with their increasing complications of technique, make it difficult to arrange adequate teaching of all branches within the limits of the medical student's curriculum. This is a serious problem with the student, but it is much worse with the trainee nurse. One solution is for her to acquire a good background of general principles and afterwards add the frills by a study of specialized monographs. For this purpose Dr. Klemme's small volume, based on his lecture notes, will be found very good indeed.

The book opens with a short but adequate account of the relevant anatomy, supplemented by diagrams from Gray and Kuntze. This is followed by a section on clinical signs and symptoms which is to be commended as simple, direct, and dogmatic. An article on the care of head cases is valuable for its excellent summaries of the nature and significance of various post-operative disturbances. The operations on the spinal cord and those performed for the neuralgias are well described in a similar manner.

Instruments and appliances are discussed at length in a separate chapter, with diagrams illustrating the best theatre layout. The details under this heading should be of great value to the nurse who is worried about preparation for a neurosurgical case.

Proof-reading has, as usual, failed to prevent an occasional misprint—there is a strange muscle, the "strapezius," on page 6—and here and there the book would gain by a translation from American into English. For instance, in a description of Parkinson's syndrome (p. 17) it is stated that "better than 85% are superimposed on encephalitis as a residual." After some cogitation the reader will no doubt decide that this means "more than 85% follow encephalitis."

While it is unlikely that other neurological surgeons will follow exactly all the technique described, the book is notable for its plain and explicit directions; the reader is never bemused by alternative methods or conflicting theories. This is a work which should be available for reference in any hospital which is out to do its best in the training of its nurses.

E. D. TELFORD.

AN AUSTRALIAN TEXTBOOK

Practical Obstetrics. By Bruce T. Mayes, M.V.O., F.R.C.S.Ed., F.R.A.C.S., F.R.C.O.G. (Pp. 306; illustrated. £2 5s.) Sydney: The Australian Publishing Co., Pty. London: George G. Harrap. 1949.

Professor Bruce T. Mayes's book is a series of clinical discussions on some of the important practical problems in obstetrics. The author had no intention of writing a complete textbook: his object was to explain and discuss the problems which are frequently encountered by Australian general practitioners. His topics have been wisely chosen, and he quite rightly emphasizes the striking work that was performed by N. M. Gregg in Australia on congenital cataract following German measles in the mother. Accounts of the diagnosis and management of pregnancy, toxaemia, eclampsia, and lower-segment caesarean section are well done, and the stress which has been placed upon the practical side is particularly praiseworthy. There is much evidence that Professor Mayes, as he acknowledges, has enjoyed writing the book, and it is certain that his work will be widely read and praised in Australia.

Great courage is required to write a book of this kind, for clinical opinions are open to criticism in detail, and this is particularly true of practical obstetrics. The Lövsett manœuvre is well described, though somewhat sketchily. Pudendal block should have been given greater prominence, particularly as the book is intended for general practitioners. Acute inversion of the uterus has been afforded a chapter, whereas more could have been written on the methods available for inducing premature labour. Drew Smythe's catheter—one of the most useful instruments in the practice of obstetrics—has not been mentioned.

Specialists should derive much pleasure from reading the book. The style is lively and many of the statements are provocative. There is much that can be criticized in detail, but the author holds one's attention from the first page to the last. The illustrations are of excellent quality, particularly the photographs of operations and demonstrations, and the line drawings merit special praise.

WILFRED SHAW.

PAEDIATRIC INVESTIGATIONS

Diagnostic Tests for Infants and Children. By H. Behrendt, M.D. (Pp. 529. £2 17s.) New York and London: Interscience Publishers Inc. 1949.

The procedures described in Dr. H. Behrendt's new volume are essentially tests for function. Convenient classification has been achieved according to the organ or system under investigation. Most sections begin with a brief description of the aim of the test succeeded by an account of the modifications caused by the age of the subject; then follow a note on procedure and an unusually large section on interpretation. Tests used at all ages are given little notice, and simple testing of the urine for

Whatever may be the explanations for the failures, it must be admitted that treatment is beset with difficulties which are enhanced by our ignorance of the normal function of the thymus. On thymectomy for tumours it is interesting that Blalock, with his limited experience, felt that the indications were definite and the results satisfactory, whereas Keynes with his far greater experience is convinced of the very much worse prognosis in these cases. In the non-tumour cases the gland appears normal on inspection, but there are histological changes. Bratton[7] has stressed a qualitative difference in the islands of parenchyma and the formation of "germ centres" in the medulla. These appearances have been noted also by Collins[8] and by Sloan[9]; similar features were present in Blalock's cases, but it is impossible to say whether they are a cause or an effect of the disease, though they are seen only occasionally in the thymus in non-myasthenic cases. Several series published in the past and culled partly from necropsy records have contained an undue proportion of tumours of the thymus: the present series shows the true incidence of tumours to be in the region of 11.5%. Bratton has emphasized that the incidence of myasthenia gravis in cases of thymic tumour is about twice the incidence of thymic tumours in cases of myasthenia.

In the future fruitful investigations may be undertaken jointly by the biochemist and the experimental physiologist. It has been shown that the serum from a patient with myasthenia gravis will interfere with the transmission of an impulse in the ordinary muscle-nerve preparation,[10] but the real cause of this effect is unknown. Biological and chemical assay of the excised glands may yield further information on this and other points. While the results of fundamental investigations are awaited it is desirable that the treatment of these cases should largely be undertaken by a highly skilled few. The technique of thymectomy has been ably demonstrated by Mr. Keynes in a film, and he is to be congratulated on his low mortality rate. To suggest that only continued observation of this steadily growing series will provide further and much-needed evidence of the true value of operation is not to detract from the brilliance of the work already done.

AIR HYGIENE

The contrast has often been pointed out between the sanitary qualities of water and air in modern civilized conditions. That a water supply should be free from infection is now taken for granted, but the more difficult problem of ensuring that the air we breathe shall be equally innocuous is not only unsolved but until recent times was almost untouched. It began to be taken seriously during the middle 'thirties, and became a subject of intensive research in this country in the early part of the war, when conditions in air-raid shelters and elsewhere seemed to favour the spread of air-borne epidemics. A team of workers directed successfully by the late Sir Patrick Laidlaw, Dr. C. H. Andrewes, and Dr. R. B. Bourdillon carried out a comprehensive study of the whole subject of air disinfection, the results of which have now been published as a Medical Research Council report entitled *Studies in Air Hygiene*.[1] This is a lengthy monograph of 356 pages, containing a large amount of highly technical information as well as descriptions of experiments and assessments of their significance which will command wide general interest.

The first essential in any such work is an accurate quantitative method of determining the bacterial content of air, and for this purpose the slit sampler invented by Bourdillon and his colleagues is evidently superior to any other device, even among those used in very extensive studies of this subject which have been proceeding at the same time in the U.S.A. This ingenious machine has been perfected and modified for different purposes, and over 40 pages of the report are given to descriptions of the apparatus and its use. Its principle is that air is sucked at a known velocity through a narrow slit immediately above a slowly revolving plate of culture medium: particles containing bacteria impinge on the surface of the medium and adhere to it. The resulting colonies can be counted, and, since the volume of air sampled per minute and the speed of rotation of the plate are predetermined, the number of bacteria-carrying particles per cubic foot of air can be calculated. The great advantage of this method is that it immediately shows the effect of any change in atmospheric conditions: an "event" such as the shaking of a blanket is reflected in a high concentration of colonies in the sector of the plate exposed at that time.

The slit sampler has been used not only in many laboratory experiments and in studies of air contamination in hospitals, but in other field trials here reported for the first time. These include investigations made in private houses, factories, and in a cruiser and a submarine at sea in time of war. The liability of naval crews to air-borne infection is notorious, and this last study shows exactly where and in what conditions the overcrowding in the crew's quarters leads to excessive air contamination, despite vigorous ventilation. Curiously enough, the bacterial content of air in the submarine was consistently fairly low; possibly this is due to adhesion of bacteria-carrying particles to oily surfaces as the air circulates through the engine-room. On the basis of such studies it is suggested that 50 colonies per cubic foot of air on blood agar at 37° C. should be regarded as a limit not to be exceeded, and that such

[1] *Spec. Rep. Ser. med. Res. Coun., Lond.*, No. 262. London: H.M.S.O

counts offer a better method than any other available of deciding whether the air of an occupied space conforms to a satisfactory hygienic standard.

The main object of most of the work described was to define efficient and practicable methods of disinfecting air which is inevitably contaminated. Tests of various methods are described in detail, followed by reasoned statements of their possible applicability in different conditions. Ultra-violet radiation has distinct spheres of usefulness, though owing to its incapacity to destroy bacteria in dust particles it may need to be combined with measures for dust suppression. Useful chemical reagents fall into four classes. Hypochlorous acid, liberated by spraying a sodium hypochlorite solution, is effective and can be disseminated by a hand-spray: its use in offices and other such buildings is considered worth while during an air-borne epidemic. Resorcinol and other related compounds are also effective and harmless, but act for only short periods. Triethylene glycol has been extensively studied in the U.S.A. and was not included in this investigation. The main contribution of the M.R.C. workers in this field has been to demonstrate the activity as air disinfectants of lactic acid and related compounds. Lactic acid itself, though harmless, is somewhat irritating, but α-hydroxy-α-methylbutyric acid is less so and has the advantage that it volatilizes adequately from an unheated surface of sufficient extent. If this substance becomes available in sufficient quantity practical trials of its use would seem to be well worth undertaking.

The keynote to the general conclusions of this report is that air disinfection is practicable only in special circumstances. There is no prospect whatever of the widespread adoption of any of these methods in public buildings and conveyances: such problems are almost insuperable, owing either to the great size of the task or to the variable conditions for which provision would have to be made. It is also emphasized that appliances used for this purpose are apt to be neglected: "people lose interest" in them, as is perhaps natural when the result of their use is at best only the negative condition of absence of infection. The nearest approach to large-scale air disinfection advocated here is the spraying of sodium hypochlorite in offices and workrooms during an epidemic, as already mentioned. It is, of course, recognized that much can be done in such places by good ventilation and lighting and by measures to suppress dust. Otherwise the indications for chemical or other special treatment of air are more or less restricted to the hospital and the laboratory, where known dangers have to be countered in a space of manageable size and in circumstances permitting full control. There is a great deal to be gained by applying these principles and methods to the control of hospital cross-infection alone, and the medical historian of the future is likely to rank the British contribution to progress in this subject as one of our main medical achievements during the war period.

NITROGEN MUSTARDS

Although the pharmacology, biochemistry, and chemistry of the nitrogen mustards were first investigated in England[1-4] reports of their use in the treatment of blood diseases came first from America[5-7] and later from this country.[8] Two aliphatic compounds of this series, HN2 or methyl-*bis* (β chloroethyl) amine hydrochloride and HN3 or *tris* (β chloroethyl) amine hydrochloride, have been used extensively in the palliative treatment of Hodgkin's disease and allied conditions. In this issue of the *Journal* Dr. J. D. N. Nabarro reports on the use of the *bis* derivative in a small number of patients over a period of three years. He found that when the glandular masses were localized radiotherapy gave better results than nitrogen mustard. On the other hand, cases in which the disease is widespread from the beginning respond better to nitrogen mustard than to radiation. Occasionally in the terminal stages of the disease a dramatic remission may occur after the administration of nitrogen mustard. Recently an aromatic nitrogen mustard, *bis* (β chloroethyl) β naphthylamine, has also been tested in the treatment of Hodgkin's disease and other conditions.[9] This last compound has some advantages over the aliphatic chloroethylamines, since it is much less toxic, can be administered orally, and does not cause the nausea and vomiting which almost invariably accompany treatment with HN2 or HN3.

The value of these substances in the treatment of cancer is still difficult to assess, but they appear to have a definite place in the palliative treatment of lymphadenopathies. In other forms of malignant disease their action is much less certain: the results obtained in most cases of cancer arising other than in lymphoid tissue and the lungs have not been encouraging. Symptomatic improvement has followed the administration of HN2 in a proportion of cases of carcinoma of the lung. Rhoads[10] was probably the first to describe a case of this kind; he studied the effects of nitrogen mustard on various types of neoplastic tissue and observed a remarkable temporary remission in a patient with anaplastic carcinoma of the lung. Out of forty-one patients with lung carcinoma treated with HN2 at the Royal Cancer Hospital[11] by Boyland and his colleagues about one half obtained symptomatic relief and showed objective signs of improvement. In these the pain, cough, dyspnoea, and general malaise were relieved, and decreases in caval obstruction, in the amount of sputum and pleural exudate,

and in the size of metastases were observed. Some patients increased in weight during treatment, and in others there was radiological evidence of improvement, with some remission of physical signs in the chest. The remissions which occurred were only temporary, lasting from two weeks to three months. Although no serious adverse reactions were noted the authors considered that nitrogen mustard does not greatly advance the treatment of carcinoma of the lung. It may prolong life in some cases, though this is difficult to assess, and it sometimes relieves distressing symptoms and thus may make the patient's remaining days more tolerable. Very similar results have been obtained by Brown and Davis in Glasgow[12] and by American workers[13]; the latter consider that nitrogen mustard may be more effective and less hazardous than radiotherapy in cases with rapidly growing anaplastic lung cancer.

That the chloroethylamines have a demonstrable clinical effect on bronchogenic carcinoma in man has been established, but it has not been possible so far to show that they have a corresponding effect on other types of carcinoma. This probably indicates some specificity of action on certain tissues. It must be remembered, however, that patients are acutely conscious of symptoms arising from disease of the lungs and of variations in their severity. In bronchogenic carcinoma a slight diminution in the size of a tumour or in the amount of tissue reaction around it may be sufficient to afford notable relief from the distressing symptoms. This apparent specificity of the nitrogen mustards is analogous to that of oestrogens in cancer of the prostate and breast and of urethane in leukaemia. These two substances are also carcinogenic: oestrogens induce mammary cancer and urethane induces cancer of the lung in mice. Boyland and Horning[14] have recently shown that the aliphatic nitrogen mustards can induce carcinoma of the lung, sarcomas, and lymphosarcomas in mice. The aromatic nitrogen mustards have induced cancer in rats. Thus the nitrogen mustards resemble the oestrogens and urethane in that they themselves are carcinogenic. Though the effects obtained with these agents are comparable, the mechanism of their action is unknown. Better understanding of this may lead to the discovery of drugs of greater practical importance than the nitrogen mustards.

SEX DIFFERENCES IN MORTALITY

A difference between the death rates of males and females has been a feature of the vital statistics of England and Wales since registration was introduced in 1836. The advantage possessed by the females over the males for all ages combined has not always appeared in the various age groups. One hundred years ago the females had a higher death rate than males at ages 10–20 and 25–45. The rate of decline in the death rates in the last decades of the nineteenth century varied in different age groups, but generally the fall was greater among females than among males. The only exceptions were at ages 5–9 and 10–14, and at the beginning of the present century the females had a higher death rate at these ages than the males. It was commonly thought that working conditions were partly responsible for the higher death rate among men during adult life. In the past 50 years, however, conditions of work have improved considerably; shorter hours are worked, and the gross industrial toxic risks have been eliminated. As a consequence of the improved standard of living the male death rate has fallen rapidly, but curiously enough the female death rate has fallen even more rapidly. At the present time the death rate of women is lower than that of men in each age group, though of course the fatality rate of some diseases is higher among women than among men. Perhaps the best-known exception to the general trend is the higher death rate from whooping-cough among female than among male children.

It has been suggested that the different social habits of males and females may in part explain the difference in the mortality rates, and this is possibly true for those diseases in which alcohol worsens the prognosis. One of the many interesting permanent features of the vital statistics of England and Wales is that the ratio of the death rate in rural areas to that of the general population is proportionately lower for males than for females. Most of the explanations put forward to explain this and other differences are too speculative to be satisfactory.

The latest inquiry into this problem is that of Johnstone and Hosker,[1] who took the Registrar-General's supplement on occupational mortality[2] as their main source of information and compared the experience of males, single women, and married women. With the exception of appendicitis every disease which causes a higher mortality among men than among women also causes a higher mortality among single women than among married women. In married women the death rates from cancer of the uterus and, after the age of 45, from diabetes are higher than in single women, but married women have a lower mortality from bronchitis, pneumonia, tuberculosis, peptic ulcer, cancer of the breast, and pernicious anaemia. They also commit suicide less often than single women. Differences between the death rates of men and women similar to those in England and Wales occur in other countries: for instance adult females have a higher mortality from diabetes than adult males in the U.S.A., Canada, and New Zealand; and in girls under 15 years of age in these countries the death rate from whooping-cough is higher than in boys. Johnstone and Hosker conclude that occupational differences must be one of the important reasons for the dissimilarity of male and female death rates.

TOXIC FACTOR IN BLEACHED FLOUR

Not quite three years ago Sir Edward Mellanby's first report[1] on the experimental production of canine hysteria was published in the *Journal*. Hysteria was produced in dogs and subsequently in ferrets[2] by feeding them with flour treated with agene (nitrogen trichloride), the flour improver and bleacher which has been in common use in this country and in the U.S.A. for the past twenty-five years. Later work on agene-treated flour fully confirmed

Mellanby's conclusions and was discussed at the time in these columns.[3] These confirmatory studies led the Food and Drug Administration of the United States Government to prohibit the use of agene, a prohibition which came into force as recently as August 1.

It was subsequently pointed out by British and American workers that the toxic agent was formed from the protein of the wheat and particularly from the gliadin fraction.[4] Since Mellanby's first observations on the subject there has been increasing interest in the identity of the toxic substance responsible. A great deal of work has been carried out by Moran and his co-workers[5] at the Cereals Research Station of the Research Association of British Flour Millers and also by other workers.[6] This has now been rewarded by the isolation at St. Albans of a crystalline substance which either is or contains the toxic factor.[7] The crystals are of needle-like appearance, melt sharply with decomposition at a temperature of 232° C. (uncorrected), and their biological activity is unaffected by further recrystallization. As in previous work, the maize protein, zein, has been used as the starting-point. In the normal way it would be said that this crystalline isolate was a pure substance, and that it only remained to establish its composition and chemical identity. But the indications are that it will prove to be a peptide; and with peptides, as with proteins, there has been a recent reminder that apparently "pure" and homogeneous crystals may turn out to be mixtures of different substances. None the less, this is an important advance, and the further progress of this work will be awaited with interest.

POLIOMYELITIS VIRUSES

The Fourth International Neurological Congress which has just ended its meetings in Paris was remarkable for a number of important and interesting communications. The discussion on virus infections of the central nervous system was of topical interest. The production of allergic encephalomyelitis and the relation of this condition to post-vaccinial encephalitis and to paralytic rabies on the one hand and on the other hand to disseminated sclerosis were the subject of a number of papers. The epidemiology of insect-born encephalitides was reviewed and a number of cases of recurrent benign meningitis were described; whether this condition is due to a virus or to allergy is still undecided. New strains of rabies virus with reduced neuronotropy have been investigated and may be of value for rabies immunization.

Perhaps the most important discussion, however, was on poliomyelitis. It was suggested that in backward countries the acquirement of virucidal bodies to the Lansing strain of poliomyelitis without overt signs of infection may result from prolonged breast-feeding whereby immune bodies are passively transferred from mother to child; the young child thus passively immunized acquires an active infection as a result of the prevalent defective sanitary conditions. The new phenomenon of virus exaltation in relation to poliomyelitis viruses was also described: doubtless more will be heard of this condition, which is the reverse of virus interference.

Few of the neurologists attending the Congress had yet realized that what is now described as poliomyelitis is a symptom complex produced by at least three distinct groups of viruses. The term poliomyelitis in fact must now be used only in a general sense, much in the same way that typhus is used to describe broadly a number of distinct infections due to different species of rickettsiae. Historic or classical poliomyelitis includes the group of viruses isolated from human faeces, nasal washings, or spinal cords. It is not a uniform group, but consists of at least four varieties which are antigenically distinct. The first of these is the Lansing type, which has been transmitted from man to monkeys and thence to cotton rats and mice. Six of these rodent-adapted strains are known, and have been isolated from patients in the Middle East and America, while virucidal bodies to these viruses have been found in Europe, America, Asia, and Africa. Three other antigenically distinct strains of true poliomyelitis virus are recognized, and there may be others, since not all material from patients dying with poliomyelitis yields positive results on inoculation into monkeys.

The second group of viruses all showing antigenic similarities and capable of producing paralysis in man comprises the Mengo encephalitis virus from Uganda, the EMC (encephalomyocarditis) virus isolated from a monkey in California, and the MM and Columbia SK viruses, which were probably derived from rodents. One of this Columbia SK group of viruses may have been responsible for an outbreak of poliomyelitis in American troops in the South West Pacific area. This group of viruses is transmissible to man, monkeys, and rodents such as mice and hamsters. These viruses can be inoculated by a variety of routes, including intramuscular injection, and they are pantropic, producing lesions in organs other than the central nervous system. Immune bodies to this virus are widely distributed.

The third group of viruses isolated in America is transmissible only to suckling mice or hamsters; distinct antigenic varieties occur, and there is now evidence that these viruses exist in Western Europe. It must be emphasized that these three groups of poliomyelitis viruses are quite distinct from the mouse encephalomyelitis viruses, often incorrectly termed "mouse poliomyelitis," which are transmissible only to mice and hamsters. Such viruses have been isolated from mice in America and in Britain. The virus infection of pigs which attacks the anterior horn cells of the cord is also distinct from human strains.

It is thus obvious that certain views on poliomyelitis will have to be revised. Some work is already in progress here on the newer aspects of poliomyelitis, but, as it now appears probable that recurrent epidemics will visit this country at frequent intervals, it is essential that a comprehensive attack should be made on these problems.

TONOSCILLOGRAPHY IN PERIPHERAL VASCULAR DISEASE

Nomenclature is an ever-increasing burden to the medical profession, and to many the term tonoscillography may seem just one more weighty straw. In this word the prefix "ton" (from τόνος, meaning tension) indicates that the height of the blood pressure is obtained simultaneously with the size of the arterial pulsations from the written record of an oscillogram. Ejrup,[1] of Stockholm, has broken entirely new ground by applying the results of

tonoscillography after exercise to problems connected with the diagnosis, prognosis, and treatment of vascular disorders of the extremities. If his findings are confirmed and his technique found not too time-consuming for general application in less expert hands than his own the early diagnosis of these conditions and the assessment of their severity should become much easier.

The idea of simultaneous automatic recording of blood pressure and arterial pulsation is not new,[2-5] but Ejrup's apparatus is both original and simple. It consists of two cuff-pressure systems actuated independently by automatic valves which inflate or deflate the cuffs at accurately controlled pressures and time intervals. The cuff applied to the proximal part of the limb to be studied—the pressure cuff—is connected to a manometer which by means of a lever inscribes a record on a continuous recording strip. The lower or pulse cuff is lightly distended at a fixed pressure, and small volume variations of arterial pulsations are recorded electrically with a movable pen attached to the same lever as the pressure cuff while the latter is steadily inflated. Diastolic pressure is recorded at the point where the form of the pulsations suddenly alters, and the point where all pulsation ceases indicates the systolic pressure. Automatic recordings are taken in this manner every 20 seconds—venous congestion being avoided by complete emptying of the cuffs in the intervals. Strict precautions are of course necessary in order to obtain comparable records. Although systolic end-points are clear, diastolic pressure is by no means always obvious in the published records.

By employing Nylin's[6] standard exercise step-tests Ejrup found that a raised blood pressure and increase in pulse amplitude in the legs invariably occurred immediately after exercise in healthy subjects. Records after exercise were remarkably constant in the same individual on different occasions, in contrast to resting records, which showed considerable variations. In patients with organic arterial obstruction, on the other hand, whether due to Buerger's disease, arteriosclerosis, or embolism, a characteristic inverse response was obtained: there was a decrease or even absence of all pulsations after exercise and a lowering of the pressure at which pulsations disappeared—i.e., an apparent lowering of the systolic pressure. In 10 cases in which the site of obstruction was determined by arteriography the level on the leg at which the inverse reaction appeared could be predicted with precision by the tonoscillograph. All but two of the 54 cases of intermittent claudication showed an inverse response, and patients with unilateral symptoms always gave a bilateral inverse response, more pronounced in the painful leg. A similar inverse reaction was also found to occur in aortic coarctation, in which, as is well known, arterial pulsation in the legs is diminished. Some of the 17 patients in this series complained of claudication, but a typical inverse response after exercise was found in every case. Treatment by the Crafoord resection operation resulted in the disappearance of the inverse reaction, and normal responses were obtained.

Ejrup's method of study of obstructive arterial disease of the extremities gives objective information which cannot be obtained by the more usual and comparatively cruder methods of oscillography. The new technique appears to make possible the accurate and early diagnosis of obstructive arterial lesions in the limbs and precise location of the site of the obstruction. It can provide confirmatory evidence of coarctation of the aorta, and it may perhaps prove valuable in determining the presence of other causes of obstruction to aortic flow, or of lesser degrees of narrowing of the aortic isthmus, in the cases in which other investigations give equivocal results and in which the femoral pulse is easily felt. The latter type of abnormality is probably more often missed than detected, particularly when associated with patency of the ductus arteriosus.[7] Ejrup claims that his method of tonoscillography is of value in differentiating functional disorders of the limbs from those due to obstructive arterial lesions, and that it can also be used to measure the extent of remission or progression of disease following treatment (of which many forms have been advocated) for arterial disorders of the extremities. Confirmation of his findings will be awaited with interest.

FUNCTIONAL VENTRICULAR FIBRILLATION

Arrhythmias originating in the ventricle, apart from isolated or short sequences of extrasystoles, are usually an expression of serious ischaemic heart disease, and are much more rarely encountered with an apparently normal heart than the corresponding disorders in the auricle. Ventricular fibrillation is, indeed, most often a terminal event, or, if survived, is an indication that the patient has not long to live. An unusual, perhaps unique, case has recently been reported by Moe,[1] who was able to record attacks of ventricular fibrillation in a man of 38 in whom no evidence whatever of organic heart disease could be discovered. After a period during which he noted palpitation the patient had a number of syncopal attacks, and a cardiogram obtained during one of these showed ventricular fibrillation lasting for 18 seconds, the patient being unconscious, the pulse impalpable, and respiration stopped. Before the fibrillation solitary extrasystoles and groups of extrasystoles were recorded, and after it a bradycardia, probably due to A-V nodal rhythm. A record on the following day showed normal rhythm with flat T waves, but on the second day these had become normal. Ten syncopal attacks were observed in one day, the number probably being augmented by treatment with injections of adrenaline; this was given on the supposition that the attacks were due to heart block. After appropriate treatment with quinidine the attacks soon ceased and have not recurred, except on one occasion when the quinidine was temporarily discontinued. Short runs of ventricular extrasystoles are the only arrhythmia which has since been recorded, and the patient remains well taking 0.1 g. of quinidine daily. Clinical and *x*-ray examination has failed to reveal any sign of organic heart disease. If Moe's interpretation of this case is correct, the possibility of functional ventricular fibrillation appears to be established.

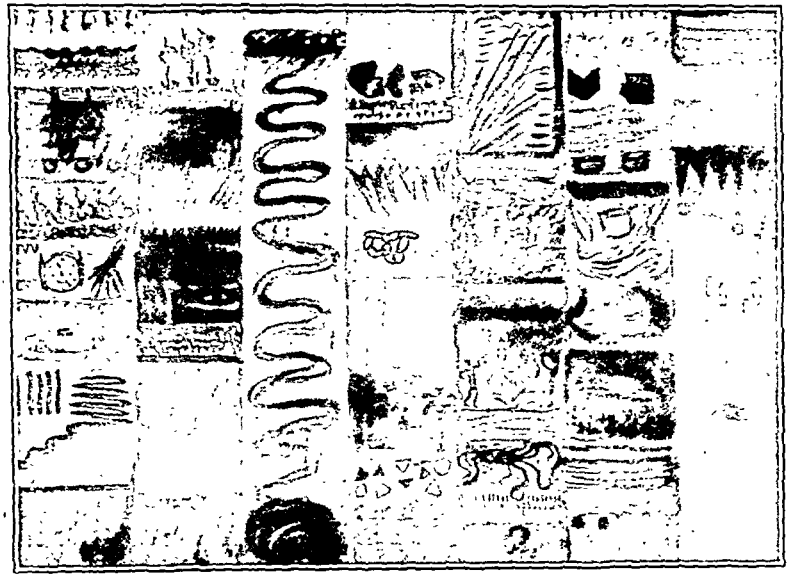

FIG. 1.—A Week.

THE PATIENT WITH THE PAINT-BRUSH

EXHIBITION OF PAINTING

An exhibition of paintings by patients from the Mental Treatment Centre, Hill End Hospital, St. Albans, was opened by Mr. Victor Pasmore at Trefoile House on September 7. The exhibition contains over 50 pictures that have been painted since the previous display 18 months ago. Most of these are the efforts of people who have painted only during a few months' stay in hospital and have never used a paint-brush before.

The paintings differ widely in character. Some are frankly objective, others are more obviously a means of emotional release. Yet each represents a form of personal creativeness and is stamped with the individuality of the painter. The artist's work is something into which his personality enters and through which his imagination finds release, which establishes painting as a useful adjunct to standard psychotherapy.

The exhibition shows also the latent powers of artistic expression possessed by those who make no pretence to special talent. Mr. Pasmore emphasized that these paintings had been executed for enjoyment and not for the purpose of analysis, and he observed that the gallery strongly resembled an exhibition of children's art. This, he said, indicated the fallacy of the opinion that fresh artistic creation was impossible after early youth.

The pictures reproduced here represent three of the different styles seen at the exhibition. "A Week" is a patient's impression in paint of seven days in his life while in hospital. "The Ravine" and "Autumn Tapestry" are imaginative studies in contrasting design.

Mr. N. C. Colquhoun and Dr. W. J. T. Kimber, medical director of the hospital, were in charge of the painting class. The exhibition is open between 9 a.m. and 6 p.m. and will continue until October 1.

Photographs of the paintings by *Sport and General*.

BRITISH ASSOCIATION

MEETING AT NEWCASTLE-UPON-TYNE

The 112th annual meeting of the British Association was held at Newcastle-upon-Tyne from August 31 to September 7, and was the fourth largest meeting in the association's history.

The presidential address on world population and world food supplies, given by Sir John Russell, formerly director of the Rothamsted Experimental Station, was commented on in a leading article in the last issue of the *Journal* (p. 585). Sir John Russell concluded that "the increased food production that may be confidently expected is more than ample for population increases at Western rates," but that "it could easily be outstripped locally where Eastern rates of increase prevail."

Sir John referred also to the induction of lactation in cows by diethylstilboestrol as the first stage in making the male redundant, and discussed the possibilities suggested in livestock breeding by the combination of artificial insemination and transplantation of ova. Edwards has estimated that by suitable dilutions the number of inseminations from one bull could rise to 10,000 or even 15,000 per annum. J. Hammond, jun., and Bhattacharya at Cambridge have shown that a cow injected with pregnant mare serum will produce a number of ova per oestrum instead of one, and attempts are now being made to transplant these into other cows, one into each, fertilize them by artificial insemination, and so get a dozen or so offspring from the chosen mother. One cow so treated might produce 75,000 ova in her lifetime, and scrub cows, otherwise of little use, might be employed as her incubators.

The Cell

The presidential address in the section of physiology was given by Professor R. A. Peters (Oxford). He discussed the cell from the point of view of the biochemist, beginning with a reminder that the development of British anti-lewisite, now available as an antidote to certain antimony and mercury compounds, as well as arsenicals, had originated in the application of a rational biochemical approach to the problem of arsenical poisoning. Like iodoacetic acid—which occupies an important position in the historical development of biochemistry—the arsenicals act by blocking a particular stage in the chain of enzyme-activated conversions which leads from glycogen to lactic acid. Such a block should lead to the accumulation of the last preceding substance. This has not been demonstrated *in vivo* in iodoacetic acid poisoning. But in the case of arsenical poisoning the accumulation of pyruvic acid has been shown *in vivo* as well as *in vitro*, thus providing a bridge between the laboratory schemes worked out by biochemists and what takes place in the human body. The participation of thiamin in the co-enzyme needed in the same stage of the glycogen–lactic acid sequence has also been demonstrated. A further such "bridge" is in the accumulation of citrate *in vivo* in fluoroacetic acid poisoning, as required in the current cyclic scheme of changes postulated to explain the oxidation of the "two-carbon" fragments formed in the metabolism of carbohydrate and fat. Such bridges are important because of—to quote Sherrington—the "mush of unrecognizably disintegrated cells" from which biochemists start their preparations; but Professor Peters added: "The onus is no longer on us if this biochemistry is not taken seriously."

Proceeding to the properties of the cell as a whole, Professor Peters recalled, first, that chemical reactions which required different conditions must be capable of proceeding simultaneously (the "microkitchen" argument); secondly, that the heart cell could respond as a whole to an amount of acetylcholine which would cover only one-six-thousandth part of its surface; and, thirdly, that the substance of the cell could be thought of as a jelly, which in essence was a fluid. He could not picture the reaction of the cell as a whole to a single local stimulus on the basis of "bags" of enzymes floating in a protoplasm which was itself without structure, and such reactions did not become intelligible until he took the view that the cell was organized as a whole. The benzene ring reacted as a whole, and its organization as a whole enabled properties to be interpreted which would be otherwise unintelligible; and so he believed it would be with the living cell.

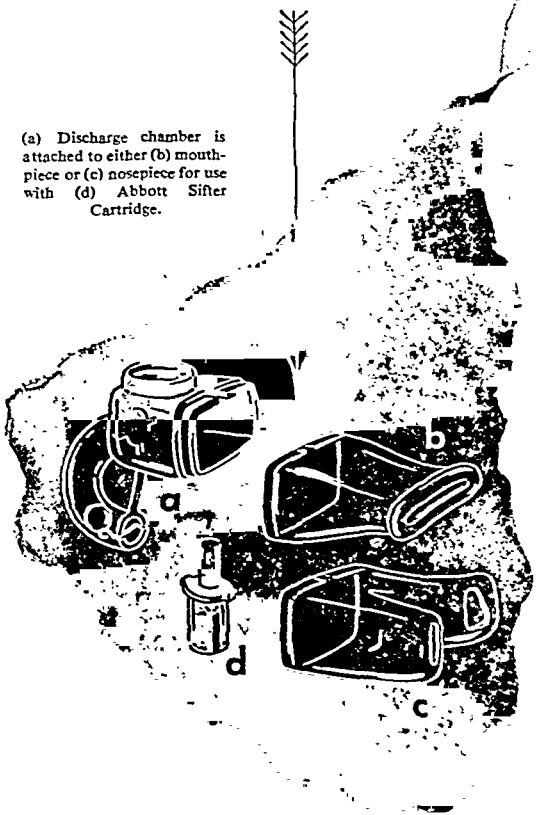
Finally, he referred to the individuality of the cell as suggested by the failure of skin grafts, even from near relatives. Such failures, he suggested, appear to be explicable only by taking the view that there is some protein constituent in the skin graft which is different for every individual. The identification of genes with enzymes he thought uncertain; and as regards cell division and growth, it seemed a better approach to tackle first the non-dividing cell.

In the discussion, to which Professor Peters's address served as the introduction, Dr. R. Barer (Oxford) described the advantages of new methods of microscopy in relation to cell structure. The phase-contrast microscope enabled the intact living cell to be studied under improved conditions, and the reflecting microscope allowed absorption measurements to be made in the ultra-violet and infra-red regions with no change of focus. He demonstrated electron-micrographs obtained by Draper and Hodge,[1] showing the localization of minerals in skeletal muscle. The essential features were the combination of long filaments running lengthwise, with extremely fine transverse striations and wider transverse bands. Professor A. C. Frazer (Birmingham) referred to possible molecular arrangements of lipoproteins which could be concerned in cell structure, and Dr. E. N. Willmer (Cambridge) spoke on "the cell from the aspect of tissue culture."

Microbial Digestion

A discussion on microbial digestion in the alimentary tract was held jointly by the sections of physiology and agriculture. It was introduced by Dr. D. P. Cuthbertson, director of the Rowett Research Institute, Aberdeen. He said that, since *all mammals so far examined had a microbial population* in the large intestine, this form of digestion must be general and normal. In carnivores, such as the wolf, fermentation on any large scale did not take place, but in most other mammals the caecum and colon had the size and the environment suitable for bacterial growth. Only substances produced outside the living microbial cell, or made soluble by autolysis of the dead cell in the large intestine, were made available to the host. In the ruminant the rumen and reticulum, the first two of the four compartments of the stomach, formed a large fermentation vat where coarse fodder material, indigestible to the non-ruminant, could be rendered available to the organism and new compounds of importance to the animal could be synthesized.

Dr. S. K. Kon (Reading) discussed the microbial synthesis of vitamins of the B complex and of vitamin K. This had been shown to take place in the intestinal tract of most avian and mammalian species, but in ruminants occurred also in the rumen, so that conditions for utilization were specially favourable. Studies with animals having permanent fistulas into the rumen showed that the rumen contents were substantially richer on a dry-weight basis than was the original diet. This applied to almost all the vitamins of the B complex which had been measured. The young ruminant, however, was without this active microbial flora during the first few weeks of life, and was as dependent on an external supply of vitamins as the dog or the rat.



American investigators had compared the input and output of different vitamins in healthy adults receiving diets deficient in one or more of these factors. The average faecal excretion of all the vitamins studied was as high on the restricted as on the normal diet, so that there must have been appreciable synthesis; but average urinary output was lower, thus illustrating the point that the value to the host of such synthesis was limited by intestinal absorption. On the other hand, an interesting condition, that of refection, could arise when certain non-ruminants received a diet rich in raw starch. In this condition animals normally dependent on a supply of vitamins in the food could dispense with it entirely. The occurrence of refection in the rat was dependent on the presence of raw starch and of starch-splitting organisms in the caecum. The animal became a vicarious ruminant, the caecum combining some of the functions of the rumen and the true stomach.

NEW

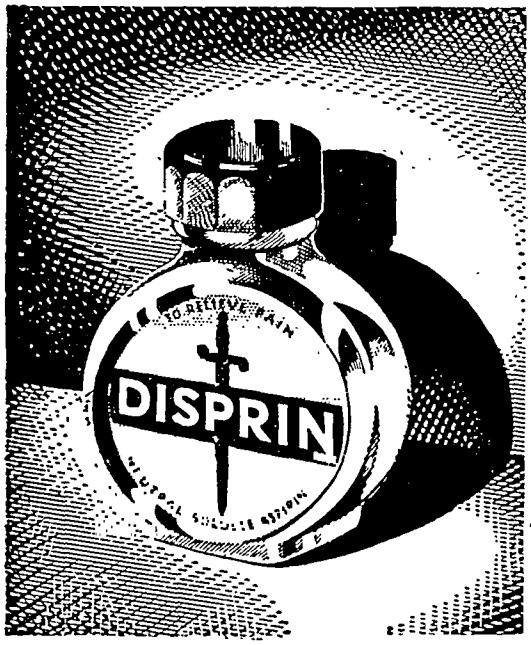
...a simplified device for Penicillin Powder Inhalation

(a) Discharge chamber is attached to either (b) mouthpiece or (c) nosepiece for use with (d) Abbott Sifter Cartridge.

Here is an inexpensive little device for penicillin inhalation therapy that requires no supplementary equipment. It is the Aerohalor—a small plastic inhaler with attachments for oral or nasal inhalation. It is used with disposable Abbott Sifter Cartridges containing 100,000 units of finely powdered crystalline penicillin G sodium.

For oral inhalation, the patient simply attaches the mouthpiece, inserts a cartridge of penicillin powder and "smokes" it like a pipe—by inhaling, removing, exhaling. Nasal inhalation is similar, using the nosepiece. The patient's respiration is the only motive power necessary.

This form of treatment is indicated for infections of the upper and lower respiratory tract produced by organisms *susceptible to penicillin. It is contra-indicated only for* infections not susceptible to penicillin, and for patients allergic to the drug. In one study, only 3 to 6 per cent reactions, none serious, were reported in over 500 cases.*



Ask your Abbott representative for a demonstration of the Aerohalor or write for comprehensive illustrated literature, ABBOTT LABORATORIES, LTD., Wadsworth Road. PERIVALE, Middlesex.

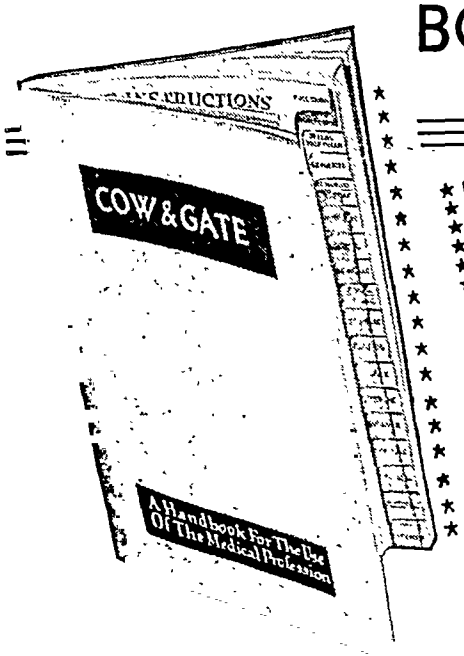
Aerohalor TRADE MARK — Abbott's powder inhaler

The problem was to neutralise aspirin

and to make it soluble. The problem has now been solved.

Aspirin is acidic, sparingly soluble, and for many subjects a gastric irritant. By contrast, its calcium salt is neutral, soluble and bland. Unfortunately, however, calcium aspirin as ordinarily presented is unstable, and thus, sooner or later becomes contaminated with the breakdown products, acetic and salicylic acids. In Disprin the problem of providing pure calcium aspirin in stable and palatable form has been solved. Extensive clinical trials show that patients can take Disprin in large dosage and over prolonged periods without suffering the disturbances, gastric and systemic, that so commonly attend intensive aspirin therapy.

DISPRIN REGD.



Neutral, stable, soluble, palatable, calcium aspirin

Bottle of 26 tablets, price 2/- including Purchase Tax · On prescription Disprin is free of Purchase Tax · Clinical sample and literature supplied on application.

Dr. J. Tosic (Rowett Institute) mentioned the ability of micro-organisms found in the rumen to assimilate cobalt and other trace elements from their external environment, and discussed the connexion of this with possible mechanisms of cobalt and other trace element deficiencies in the ruminant.

Pernicious Anaemia

Discussion of microbial digestion led into a further discussion on folic acid, vitamin B_{12}, and anaemia. Vitamin B_{12} is the first pure substance of biological origin in which cobalt is contained.

Dr. E. Lester Smith (London) stated that knowledge of the absorption by ruminants of vitamin B_{12}, probably made by bacteria, had come to light through work on the need of chicks and other animals for a factor present in animal but not in vegetable proteins. It was then found that this factor could be synthesized by certain bacteria, and about the same time it became clear that it was none other than vitamin B_{12}. One organism that made useful amounts was *Streptomyces griseus*, already in commercial use for streptomycin production, and crystalline vitamine B_{12} has already been isolated from this source.

Dr. C. C. Ungley (Newcastle) distinguished between the megaloblastic anaemias according to the presence or absence of gastric atrophy. In Addisonian pernicious anaemia the effects of vitamin B_{12}, given by various routes and with and without gastric juices, suggested that it permitted the detoxication of the haemolytic factor. Vitamin B_{12} was also as effective as liver extract in the treatment of the neurological changes. Pteroylglutamic acid (folic acid), on the other hand, was only temporarily or partially effective. But in the second group, without gastric atrophy, pteroylglutamic acid was effective in small doses, and vitamin B_{12} even in large doses was either ineffective or only partially effective.

Planes of Nutrition

Planes of nutrition in livestock were discussed in the section of agriculture in relation to shortages of feeding-stuffs and the economic return, measured by the conversion of one foodstuff into another. Mr. R. W. Pomeroy (Cambridge) spoke of sheep and pigs. In sheep, a low plane of nutrition during early pregnancy had no effect on the size of the foetus, but a high plane during late pregnancy made it more likely that the lamb could be sold as a "fat lamb" direct from the ewe. Such a combination therefore gave the greatest return from available extra feeding-stuffs. In pigs, with more numerous progeny, the problem arose of the feeding of the young pigs as well as of the sow. Young pigs benefited most from a high plane of nutrition up to 100 lb. (45 kg.) live weight; less from a high plane of nutrition thereafter. The most efficient conversion of foodstuffs was through a high plane of nutrition followed by a low, and the difference compared with the reverse procedure was as much as 70%. Sows usually proceeded without intermission from lactation to pregnancy, and a high plane of nutrition was needed for recovery from lactation. With less certainty, it was argued that a high plane of nutrition during late pregnancy was undesirable, on the grounds that excessive lactation was promoted and also a clumsiness of movement which could be dangerous to the young pigs.

Dr. S. Bartlett spoke of dairy cattle. He suggested that cows, cowmen, and examination candidates were all of the opinion that there was only one way of feeding dairy cattle, and that was as laid down in official publications. There were discrepancies between British and American figures for extra milk yield; but if farmers could be induced to supply extra food, and cows to eat it, an adequate physiological response should be obtained.

In the section of physiology Dr. R. Passmore (Edinburgh) summarized the results of a dietary survey of 298 students under 21 years of age which had been carried out by the Department of Public Health and Social Medicine of the University and the Scientific Advisers' Divisions of the Ministry of Food.[1] The minority of students on an ill-balanced diet were evenly distributed among both sexes and among those living at home and in lodgings, the diets of those living in university hostels being on the whole well-balanced. From interviews with students it was concluded that even at university level there was a real need for elementary health education, ignorance being more important than lack of money in determining bad feeding.

[1] A. H. Kitchin, R. Passmore, M. Pyke, and G. M. Warnock, *Brit. J. soc. Med.*, 1949, 3, 10.

Psychology and Industry

Sir Godfrey Thomson's presidential address to the section of psychology consisted of a criticism, on the ground of method, of the tendency to multiply mental factors. His general attitude was that factors of different sorts were useful and vivid additions to the psychologist's vocabulary, but that "they are not at all unitary and only partially innate, being built up in the individual mind by many external influences." Probably the general level of intelligence owed most to heredity—a "ceiling" which the individual might fail to reach but could not surpass. With other so-called mental factors, Sir Godfrey suggested that much more was due to environment.

A discussion on human problems in the design of machinery and working methods was opened by Dr. N. H. Mackworth (Cambridge). Dr. G. B. Frisby (National Institute of Industrial Psychology), who followed, argued that satisfaction in work should be regarded as a basic requirement. A machine limited by its design the freedom of action of the worker, and so did methods of manufacture, even in assembly and other manual work. Lay-out, special jigs, and tools all determined that the job should be done in one way decided not by the worker but by the production engineer. This favoured the "we—they" attitude. The size and complexity of the individual task were also reduced, and the tendency had been to accept as inevitable both this increased subdivision and the reduced satisfaction that went with it. There was a need for research on the nature of the satisfactions which could be felt from work. For example, could pride in skill persist where the creative element had disappeared? In any event, if the production engineer proceeded in his breakdown of jobs beyond the point at which loss of satisfaction occurred for the majority of his workers, then efficiency would decline. Speed, shown by the stopwatch, might increase, but persistence might fall, and labour wastage and absenteeism might increase.

Piltdown Man

The status of the Piltdown skull, found by Mr. Charles Dawson a few miles north of Lewes in 1908, seems to have been finally settled by two communications to the section of anthropology. Dr. K. P. Oakley (British Museum) presented the results of the fluorine test by which the age of bones found in the same geological sequence can be roughly compared. Skull and jaw had proved approximately contemporary—thus settling one argument which has persisted even to the present year—but neither was likely to be older at most than 100,000 years. There could be no question, therefore, that Piltdown Man and, say, Pekin Man could be approximate contemporaries.

Dr. Robert Broom (South Africa) reported in a written communication that he had independently reached the conclusion that the Piltdown jawbone belonged to the same individual as the brain case; that this was a big-brained type of man which evolved on a quite different line from true *Homo*; and that the "simian shelf" in the lower jaw was probably an indication of parallel evolution rather than of close affinity with the anthropoids.

THE LISTER INSTITUTE

Macbeth exclaimed, "Bring me no more reports; let them fly all," and in the office of a medical journal it is difficult not to sympathize with him. Of some reports it can be said that their copiousness is in inverse proportion to the importance of what they describe; but of others that their volume is as meagre as the work itself is outstanding. The latter is true of the annual report of the governing body of the Lister Institute of Preventive Medicine for 1949. This is a thin pamphlet of 13 pages and describes the year's work of a staff of about 50 highly skilled research workers, all engaged on special lines of study. The report is so short that the work done at Chelsea

Bridge Road remains largely uninterpreted, even to the expert engaged on a parallel line of research. It is true that most of the work is a continuing study—that is to say, reportable results are not necessarily forthcoming in a particular year—but the pursuit should be worth reporting as well as the goal. To name only a few of the lines of research which are proceeding makes their potential importance evident.

Work is being carried out on the factors concerned in the virulence of *Haemophilus pertussis* for mice, and the influence of such factors on the immunizing properties of whooping-cough vaccines; on methods of preserving vaccinia virus without the use of refrigeration; on precipitating antisera against the blood of man and animals with the object of identifying blood meals of blood-sucking insects; on the haemolysis of erythrocytes from different species of animals by clostridium toxins; on the nature of the linkages in gramicidin most susceptible to acid hydrolysis; on the examination electrophoretically of a group of sera from cases of pneumoconiosis; on factors in blood clotting; on the metabolism of nicotinamide and related compounds as affected by diet—and on many other lines of investigation in the bacteriological, biochemical, biophysical, and nutritional fields.

Some of the nutritional studies are interesting. One of them is on the effect of vitamin A on gastric conditions. Cases of peptic ulceration, or of gastric pain without ulceration, treated with vitamin A as out-patients at the Royal Free Hospital have been followed up. Healing of the ulcer has been demonstrated radiographically in some cases. Continuous treatment for six to ten weeks seemed the most satisfactory, and prolongation of continuous treatment for long periods caused relapse in a few cases. Sometimes, after an interval of six to twelve months after treatment, pain would return, and another course of six weeks' treatment was then necessary. Cases studied at the Medical Branch of the General Post Office at Mount Pleasant have also been followed up, and the results confirmed those obtained at the Royal Free Hospital. Vitamin A has been studied further in relation to the stomach of rats. Search has been made for the factor which prevents proliferation of the gastric epithelium when the animals are deprived of this vitamin. Efforts to find the factor in casein prepared in various ways have proved unsuccessful, and recourse has been made to certain vitamin-A-deficient flour diets. Flour of 85% extraction has been used, and in a preliminary experiment with 18 rats epithelial proliferation, though not entirely absent, was very much less than with any other diet tried. It did not appear to be of significance whether the flour was bleached or unbleached.

The Blood Products Research Unit of the Institute has issued during the year large quantities of dried human plasma and plasma fractions for clinical use, also 2,500 ampoules of gamma globulin for clinical trial in cases of measles.

It is announced that Lord Horder, owing to the increasing demands on his time, has resigned his seat on the governing body after fourteen years' service. Dr. A. N. Drury has been appointed in his stead. The governing body again records its appreciation of the continued co-operation and collaboration of the Medical Research Council, the work of whose external scientific staff is described in the report.

DRUG ADDICTION IN BRITAIN

REPORT TO THE UNITED NATIONS

The British Government's Report[1] for 1948 to the United Nations on the traffic in opium and other dangerous drugs was published last week. Approximately 395 addicts are known to the Home Office—198 men and 197 women. Of these, 112 are doctors, 3 dentists, 1 a veterinary surgeon, and 3 pharmacists. Information about addicts is generally obtained by Home Office inspectors and by the police in the course of normal routine inspections of the registers kept by wholesale and retail chemists, and by visits to doctors who are prescribing for patients who are addicts. All the addicts are reported to have obtained their supplies from legitimate sources—i.e., on prescription. During the year eight doctors were convicted of violation of the narcotic laws, and in six of the cases the authority to possess, supply, and prescribe dangerous drugs was withdrawn by the Secretary of State. Eighteen men and six women were reported as having been cured of their addiction during the year; eleven of these were doctors. Approximately 12% of all the addicts are reported to be using pethidine either alone or together with another drug.

The only regular illicit importation of dangerous drugs to this country is carried on by merchant seamen, who are usually Chinese, Indian, or African. The drugs they bring in—mostly Indian hemp and opium—are used almost entirely by themselves or by their fellow countrymen. This illicit traffic is largely confined to the seaport towns, but during the year three negroes were arrested in Birmingham for being in unlawful possession of Indian hemp. It was discovered that they had obtained their supplies in Liverpool, where three other men engaged in trafficking were arrested. There was only one case during the year in which drugs from legitimate sources were suspected of having been diverted into the illicit traffic. In this case two men, both addicts, were proved to have forged certificates showing that accomplices of theirs were registered as drug addicts abroad. The accomplices were then introduced to two doctors in London who, because of the forged certificates, were induced to prescribe heroin and cocaine.

Supervision is exercised by Home Office inspectors over persons authorized to possess and use dangerous drugs. Inspection of retail pharmacists is carried out as a matter of routine by the police forces throughout the country. The inspectors, who advise and assist the police in this work, also visit retail pharmacists either casually or in the course of special inquiries. Doctors' records of dangerous drugs may be inspected by regional medical officers, who are ready to give advice on cases of addiction. If a doctor, dentist, pharmacist, or veterinary surgeon has been convicted of irregularities connected with the supply of dangerous drugs the Secretary of State is empowered to deprive the offender of his authority to possess, supply, or prescribe the drugs.

During the year pethidine and amidone were added to the list of drugs for which a separate register or part of a register must be kept. No modifications in the administrative arrangements for implementing the information convention were made during the period.

Nova et Vetera

THE PITCAIRNS

Three Pitcairns have acquired places in medical history—Archibald (1652–1713), William (1711–91), and David (1749–1809). David was the nephew of William, and William was of the family of Archibald, although what William's precise relationship to Archibald was, Munk does not say. Archibald Pitcairn, according to Munk, was "celebrated as the founder of the mechanical sect of medicine." This is hardly accurate: Borelli (1608–79) came before him. Borelli, however, was not much of a physician, and Haeser assigns to Archibald Pitcairn the honour, if it is an honour, of carrying the application of iatro-mechanical physiology in practical medicine to its highest point. Haeser gives Alexander Pitcairn a page and a half, but had probably formed the opinion—certain to be entertained by a modern reader—that iatro-mechanism was rather silly. He permits himself to say that Pitcairn, "like all one-sided theorists," was apt to swear by empirical remedies, and instanced the human skull and earthworms as part of Archibald Pitcairn's pharmacopoeia. It is, humanly speaking, certain that neither William nor David Pitcairn ever prescribed either, but William had great faith in opium and there is a story that his nephew David, when a medical student in Edinburgh, saved the life of Professor William Cullen's son by conveying his uncle's advice to administer laudanum freely.

Haeser has nothing to say of William and David Pitcairn, neither of whom published anything; both kept such theories

as they had to themselves. William Pitcairn prescribed opium freely, but David seems to have had little faith in drugs. Of him it is said that when a young physician commented on the inertness of his prescription in a case of consumption he replied: "The last thing a physician learns, in the course of his experience, is to know when to do nothing, but quietly to wait and allow nature and time to have fair play in checking the progress of disease and gradually restoring the strength and health of the patient." Not so terse as Hippocrates, but Hippocratic.

Uncle and nephew were esteemed by the public and their colleagues. William Pitcairn was president of the Royal College of Physicians for ten years, 1775–85, and retired from practice in 1784, when he was appointed treasurer of St. Bartholomew's Hospital. He was physician to the hospital for 30 years (1750–80). His nephew David followed very closely in his steps; he was elected physician to St. Bartholomew's in 1780. If Munk's dates are right there seems an irregularity in the hospital's practice, because in 1780 David Pitcairn was neither M.D. (he graduated M.B.Cambridge in 1779 and M.D. in 1784) nor a licentiate of the College—he was admitted candidate in 1784 and Fellow in 1785. It is possible that, as his uncle was president, the College did not enforce its legal rights.

David Pitcairn followed his uncle as physician to Bart's within a week, and might well, after a somewhat longer interval, have succeeded him as president of the College had not his health failed in his fiftieth year. Residence for 18 months in Portugal was followed by improvement, and on his return to England David Pitcairn partly resumed work, but his health was broken and he died in 1809, two years younger than his uncle was when first elected president of the College.

As the judicious reader will have noted, Munk, whom I have followed, could add little to what was so well said in *The Gold-headed Cane*, and Macmichael (1784–1839) was a very young man when David Pitcairn died. The only estimates by contemporaries which survive are the eloges of deceased Fellows, then pronounced not by presidents but Harveian orators and not in English but in Latin (in not very good Latin, according to a better judge than I am). But an elogist is likely to dwell on good traits. Cadogan emphasized William Pitcairn's kindness to his professional colleagues, Heberden (the younger) David Pitcairn's excellence as a clinical teacher and his kindness to hospital patients. Great teachers are as rare as great investigators and inevitably fill less space in medical histories. Trousseau is mentioned by the learned Haeser only as a French physician influenced by German medicine, but any reader of his *Clinique Médicale* (1861) can understand why he impressed medical students. David may be the greatest of the three Pitcairns, because a tradition established by a fine teacher outlives him and still works for good when he is forgotten.

Heberden co-ordinated the treatment of the poor and the power of the teacher in his eloge of David Pitcairn (pauperes pene innumerabiles cura sublevavit, multosque discipulos, praeceptis ex re natis, ad medicinam faciendam optime instituit). Another great Bart's teacher, Peter Mere Latham (1789–1875), was in the succession. Latham and Trousseau, in eloquent words which have survived, impressed on their pupils the importance of *humanitas*, which, like *honestas*, means so much more than the English derivative. The Bob Sawyers of a century ago needed that lesson more than their great-great-grandchildren. Callousness and brutality in students are no longer to be feared. But in an age of gadgets and official forms, when "case" and "patient" are used as synonyms, it may still be worth while for the young physician to borrow a friend's—or his grandfather's—"Lewis and Short" and look up *humanitas*.

MAJOR GREENWOOD.

The Pharmaceutical Society of Great Britain was represented at the Assembly of the International Pharmaceutical Federation in Amsterdam in August by the President, Mr. H. Clement Shaw, Professor Brindle, Professor Todd, Dr. J. M. Rowson (who read a paper at the Assembly), Mr. E. A. Brocklehurst, Miss M. A. Burr, Mr. J. F. McNeal, and Mr. H. N. Linstead (joint secretary). Mr. F. W. Adams (joint secretary and registrar) accompanied the delegation.

Correspondence

Distinction Awards

SIR,—While I am wholly out of sympathy with the theme and spirit of Dr. H. E. A. Boldero's letter (September 10, p. 594), yet I can still congratulate him upon having packed into its short space more sophistries than I should have thought possible save in an election address.

All the usual rationalizations of the temperamentally acquiescent appear there in their tawdry unreality. The proposition that because a national health service is a desideratum, therefore all that is now happening is "the wish of the people," whereas, as everyone knows, it represents nothing more than a Cabinet policy; the implication that, save for a few unpractical reactionaries, the entire profession is hastening to help and guide "the Government of the day" (how familiar the phrase is to Fellows of the Royal College of Physicians); and, worst of all, the sinister reminder to young consultants that unless they go quietly they will, financially speaking, have their necks wrung like chickens. "Bow to the inevitable, there is a cheque behind it" is in effect Dr. Boldero's stirring appeal to youth.

Against this too familiar pattern there rises to meet our ears the orchestra of complaints and lamentations against the working of the Health Service that echoes loud in every issue of the *Journal*, coming from every professional group save—so far—the graded consultants. The body of general practitioners festers with resentments, and the graded hospital officers have grievances not less bitter. To this cacophony there will surely be added in due time the complaints of those consultants who are dissatisfied with their "distinction" gradings, and if these go underground and are not heard in the medical press they will be none the less deeply felt and will destroy the harmony of medical staffs. All this is very different from Dr. Boldero's pleasant fantasy of a profession striving almost unanimously to help the Government to perfect the manifestly imperfectible. Surely if things were as Dr. Boldero would have us believe we should be piping more tunefully and with a better grace.

It is possible that I am in a minority amongst my fellow consultants on this issue, for the power of money is great; but I believe that the only real distinction now left to the consultant is to be of this select minority and to remain *hors concours* in the competition for State subsidies.

If consulting practice as we have known it at its best is to die, it will not be because of the fears of the younger men but because the old men who should have foreseen and averted their painful dilemma lacked vision and the spirit of courageous leadership. To be acquiescent in the drift towards the helotry that faces us is not, *pace* Dr. Boldero, to be constructive. And to bow to the inevitable—that we have made such by bowing to it—is not the high spot of heroic virtue. At least, we did not think so in 1940.—I am, etc.,

London, W.1. F. M. R. WALSHE.

Co-operation with Institutes of Education

SIR,—In your educational number Professor W. R. Niblett (September 3, p. 526) urges co-operation between institutes of education and medical schools, and you comment favourably on this suggestion in a leading article. I should like to endorse the great value of such co-operation. Soon after the start of the Institute of Child Health at the Hospital for Sick Children, Great Ormond Street, in 1946, contact was made with the Director of the Institute of Education of the University of London. Soon afterwards a standing joint committee was formed to deal with matters of mutual interest. There is a free interchange of staff for teaching purposes, and the Child Care Training and Research Scheme at the Fourdling Hospital site is a joint effort of the two bodies. Moreover, the Institute of Education has organized a series of conferences on teaching methods for the staff of the Institute of Child Health, when selected speakers opened discussions on such subjects as the use of the lecture, the value of tutorials, visual aids, and voice production, which were extremely helpful. The need

for collaboration with an institute of education is perhaps more obvious for a school or department dealing with children than for those covering the older age range. I am certain, however, from our own happy experience that Professor Niblett's advice should be widely followed. It is perhaps immodest to add that the fruitfulness of the collaboration is not, I think, one-sided.—I am, etc.,

Institute of Child Health, University of London. ALAN MONCRIEFF.

Essential Hypertension in Pregnancy

SIR,—Mr. R. H. Paramore writes (August 27, p. 486) that he is not satisfied with the statement made by Mr. John Sophian (August 6, p. 335) in the sense that vascular spasm is the primary change inducing hypertension and that it is the cause of renal cortical ischaemia.

To this concept Mr. Paramore opposes his hypothesis that anuria, whether in the pregnant woman or not, is not the result of a decreased intrarenal blood flow, but on the contrary that it is due to an increased blood flow to the renal medulla, which maintains the "obstruction" of the uriniferous tubules. He attributes to the reduction of the medullary blood flow the benefits derived from repeated spinal anaesthesia, which he so wisely advocated more than twenty years ago. He is probably right in this, but perhaps not in the sense that he thinks it to be.

In favour of his views he mentions Clifford White's histological findings in renal tubules which were obtained from "a minute piece of the kidney" (in White's words) from two uraemic patients; indirectly, he also seems to value the fact that he did not find "any reference to the effect of the secretion of urine on the blood flow through the kidney" in the book *Studies of the Renal Circulation*, in which I was a collaborator. He considers this omission of fundamental importance. While I hope to contribute soon to the discussion of these and other related problems in a more extensive manner, I must now advance that on p. 36 of the English edition of our book there appears a reference to our observations on the correlation between a diminished urine flow and a diminished cortical circulation.

As our immediate purpose was to study the renal circulation and not the renal function we were for the moment satisfied with the confirmation of the findings made more than a century ago by Claude Bernard, who showed that the electric stimulation of the splanchnic nerves caused the urine flow to decrease or even to cease, an observation which has been untiringly repeated since then. We also dispose of a copious mass of information about the renal vascular response to this and other types of stimulus, such as certain hormones (adrenaline, "pituitrin," "pitressin"), toxins from staphylococci, streptococci, and *B. welchii*, and even to simple oxygen lack. The effect of all these apparently different vascular stimuli is to cause constriction of intrarenal vessels. If the stimulus is sufficiently powerful it might cause total renal ischaemia, whereas if the stimulus is of a moderate nature it might only cause a reduction of the calibre of the more excitable intrarenal vessels, such as those of that part of the cortex which is not anastomosed with either perirenal or medullary vessels. It is a consequence of the cortical arterial constriction that the medullary vessels appear engorged in some cases of fatal anuria. In others the whole of the kidney suffers from anoxia.

As a surgeon who has had for many years the misfortune of being confronted with serious forms of traumatic and surgical shock I have difficulty in understanding how shock might help in increasing urine flow. Up till now kidney failure in shock has been one of the greatest surgical problems. We know through a series of careful clinical and experimental observations that "primary" or immediate shock is characterized by renal vascular spasm (see among many others the papers from the school of van Slyke). Probably this vascular spasm is beneficial, as it reduces both the circulatory area of the vitally non-essential organs and it also helps to maintain the blood volume by stopping urine formation.

After a certain time the renal anoxia caused by vascular spasm gives way to that of peripheral collapse of "secondary" shock. In this later stage urine flow is interrupted, not by a functional and reversible mechanism such as arteriolar spasm, but by damage to that part of the kidney which is more sensitive to the lack of oxygen—that is, the tubular cells. I cannot understand how high spinal anaesthesia may contribute to the flow of urine otherwise than by releasing the arteriolar constriction. This seems to be the mechanism of the kidney which "obstructs" the flow of urine. Mr. Paramore gave an early answer to this most pressing necessity by advocating the method which in its more elaborate modern form has in the hands of Dr. Robert A. Hingson produced such satisfying results.—I am, etc.,

Oxford. J. TRUETA.

Medical Education

SIR,—Having read the series of articles in your educational number (September 3) I feel that consideration has been directed in the main too much towards the route and too little towards the destination. The ultimate aim must be the production of a general medical practitioner, yet this point certainly was not emphasized in your *Journal*. Specialization follows after qualification.

Are we in danger of forgetting this? It would appear that we are, since more and more time is being asked for and undue importance attached to the subsidiary clinical subjects. Instead of their being separate entities they should be fused and administered under the general headings of medicine, surgery, obstetrics and gynaecology, and pathology. For example, *place paediatrics under medicine, despite the recent development* of professorial chairs in paediatrics. Maternity and child welfare and venereal diseases would come under obstetrics and gynaecology, and haematology would assume its rightful place in the more general subject, pathology. These few examples may irritate specialists in the subjects mentioned, but they serve to illustrate the point I wish to make, that with integration would come realization of sphere of influence. And the time has come for specialists in certain subjects to realize that in their subject the requirements for the medical student may be generalizations rather than minutiae. A director of clinical studies would go far to make fusion and administration less difficult.

Professor W. Melville Arnott (p. 497) fears that the increased number of students may result in large ward classes. This need not be so if a considerable part of the present wastage of clinical material is utilized. The greater the number in the class often means the more competitive the spirit in that class. The area union of hospitals should make this problem easy of solution provided the universities are willing to pay their teachers a rate of salary comparable to that in the National Health Service and thus attract sufficient numbers. So far as lecturing is concerned, to lecture to a few is most discouraging. I had the privilege recently of attending a lecture to a class of 250 students of obstetrics in Sydney, Australia. There Professor Bruce Mayes has a microphone installed in his lecture room! The 250 were the survivors from a class of nearly 600 that had started the course. Yet I was assured that each student delivered more than thirty obstetric cases him- or herself—a triumph for administration and utilization of available material.

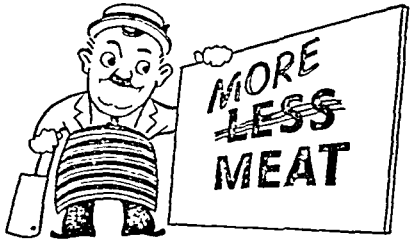
Let us unite, even at the sacrifice of personal pride in the importance of one's subject, to integrate the subjects in the curriculum so that we produce in the end a man or woman trained in the essentials for general practice. In the words of *The Times* (August 27), "If general practice is not raised to a new level of competence—some would say, restored to its rightful place—the whole of British medicine will suffer."—I am, etc.,

Oxford. G. GORDON LENNON.

Postgraduate Education of General Practitioner

SIR,—The new academic year is approaching and in consequence much is being heard of undergraduate education. I feel it is also an opportune moment for something to be said about the postgraduate education of the general practitioner. If the general practitioner is to play his part in modern medicine it is essential that he should be able to maintain his contact with

"the patient who won't fit in...."



The mentally depressed patient who will neither "fit in" with his surroundings nor co-operate in treatment presents a stubborn and increasingly widespread problem in these difficult days. In such a case, a drug is called for that will improve the patient's mental outlook and overcome his inertia. The answer, both in sickness and in convalescence, is provided by the remarkable stimulant effect of

'Tabloid' 'Methedrine'

More—or less—meat? While the hopes of Britons fall and rise with the ration—as its value changes from 1/2d. to 10d., to 1/1d., to 1/4d.—must their nourishment fluctuate, too? This question looms large in many minds.

Well, an ounce of beef contains about 4.5 grammes of protein—that essential nutrient. So every extra ounce of meat provides *that* much extra protein, and every ounce lopped off the ration deprives us of *that* much vitally needed food.

If meat were our only source of protein, this fluctuating ration *could* be serious. But it's fortunate that there are other just as useful foods, and correct nutritional technique at the moment is to rely on them for protein, accepting the meat ration, whatever its size, as a weekly treat! The "other foods", of course, being milk, cheese, eggs, fish .... *and Bemax.*

For patients requiring a generous protein intake, Bemax will be found an invaluable supplementary food. Its protein content is higher than that of most other common foods, and amino-acid analysis shows its protein to be more like that of 'animal' than 'vegetable' origin. Actually, weight for weight, Bemax supplies *more* protein than does lean beef, and comparison of essential amino-acid contents shows it to be of *equal protein value* with beef.

The recommended daily ounce of Bemax supplies in a week more protein than the meat ration (taken as steak). *This in addition to its well-known vitamin contents!*

VITAMINS LTD., UPPER MALL, LONDON, W.6.

foundation of trouble-free weaning

The popularity of Farex is based on sound results . . . practical success as an infant weaning food over many years. Here is a food that provides a sensible balance of protein, fat and carbohydrate; a sufficiency of mineral salts; and adequate vitamin nutrition —all factors of first importance in the infant diet. *Three* cereals are blended in Farex with extra iron, calcium and vitamin D, forming a bland smooth food ideally suited to the young digestion. Indeed, Farex mixed with milk and sugar can be given to babies just as soon as they turn the scales at 15 lbs., even if this happens as early as the fourth month. Farex is ready cooked and is therefore very quickly prepared. It is unflavoured, too, which means that it can be mixed with strained vegetables, bone broth, fruit juices and so on. And, incidentally, Farex is very economical.*

its rapid advance. Much lip service is paid to his importance, but I feel that too little attention is given to the means which would enable him to justify that importance. Fortnightly or week-end courses, which appear to be the main suggestions to this end, can never be effective; they are liable to provide the practitioner with a mass of information of which at the best he could absorb a little and which at the worst would only confuse him further.

There are, to my mind, two possible answers to this problem. First, the long-term answer, the integration of the general practitioner with the local hospital. This, though a formidable problem, is not impossible and might bring advantages from the patient's point of view. Secondly, short five-working-day periods of attachment to a moderate-sized hospital where each day men of the standing of clinical tutors could teach for a period of three hours on selected cases. I feel that three hours' teaching is as much as most people can use without boredom. The rest of the day the practitioner could partake in the work of the hospital, much as do junior housemen and clerks. The advantage of the five-day period is that few men could not spare this once or twice a year.

In a further effort to enable the general practitioner to keep up to date I would like to suggest that, at periods appropriate to the advances in the subject, monographs similar to that on sulphonamides published by H.M. Stationery Office should be made available. Unless one is conversant with the particular specialty, articles such as are printed in the various journals cannot be evaluated by the practitioner. I feel that the monograph should not be by an individual, who may have a personal bias, but by a committee, who could state the present body of fact and belief on which the bulk of practice must be based.

This, as behoves a letter, is merely in the form of a suggestion which will I hope stimulate our teachers to consider what can be done to help the general practitioner to fill adequately his place in the new medicine which is before us.—I am, etc.,

Blackburn, Lancs FRANK LIVESEY.

Training in Public Health

SIR,—I read with interest your leading article (September 3, p. 523) on training in public health. It is indeed encouraging to note that you have such confidence in the future of the public health service—a view which is shared by few at present engaged in preventive medicine.

I believe there to be a great future in public health, but with this assumption—namely, that the preventive approach will be introduced more and more into the medical curriculum. In this connexion much of the D.P.H. course could usefully be taught to undergraduates. If this were so our colleagues in the curative branches of medicine would not only have some sympathy towards our motives but would give us their active co-operation. When all doctors have instilled into them the importance of social and environmental factors in the causation of disease, and when we can all work together in health centres, I see no reason why G.P.s and specialists alike should not constantly seek the advice of the M.O.H. on the social and environmental problems of their patients. The M.O.H. could then indeed become a "*true specialist in preventive medicine.*"

This brings me to an extract from your article: "Financially the rewards of a career in public health will always be less than clinical medicine can offer." Why? Is it not somewhat illogical to state categorically that the financial rewards of preventive work must always be less than those for curative work? Must prevention take second place to cure? Would not the only just solution to the salaries question be to take the three main branches of the profession—general practice, public health, and specialist—and give them a common minimum and a common maximum and work out a salary structure in each within the same limits? The newly qualified doctor could then choose his career according to his inclinations without being biased by financial interest.

The opportunities in public health are infinite—one can only hope they will be grasped with both hands. The first round of the public health battle, that against epidemic infectious disease, has to a great extent been won. Now we can turn our energy against the social and environmental factors in the aetiology of other forms of disease. Shall we move along these lines? I hope so, but I believe the bias of medical education will be the deciding factor.—I am, etc.,

Chester. B. G. GRETTON-WATSON.

Goethe, an Appreciation

SIR,—Another great admirer of Goethe's *Faust*, I have been surprised to see that none of those who recently contributed in expressing their love of this unique work quoted the scene from Part I which has a direct bearing on medicine and which would have fitted so well into your educational number. Having pulled the scholar's leg mercilessly over the choice between logic, metaphysics, and law, Mephistopheles continues as follows (in Bayard Taylor's translation):

"To grasp the spirit of Medicine is easy:
Learn of the great and little world your fill,
To let it go at last, so please ye,
Just as God will!
In vain that through the realms of science you may drift;
Each one learns only—just what learn he can:
Yet he who grasps the moment's gift,
He is the proper man.
Well made you are, 'tis not to be denied,
The rest a bold address will win you;
If you but in yourself confide,
At once confide all others in you.
To lead the women, learn the special feeling!
Their everlasting aches and groans,
In thousand tones,
Have all one source, one mode of healing:
And if your acts are half discreet,
You'll always have them at your feet.
A title first must draw and interest them,
And show that yours all other arts exceeds;
Then, as a greeting, you are free to touch and test them,
While, thus to do, for years another pleads.
You press and count the pulse's dances,
And then, with burning sidelong glances,
You clasp the swelling hips, to see
If tightly laced her corset be.
Student: That's better now! The how and where one sees.
Mephistopheles: My worthy friend, grey are all theories,
And green alone Life's golden tree."

Has anyone ever poked better fun at our respected brotherhood? And as to Part II, I entirely agree with Mr. H. Corsi (September 3, p. 546): it is by no means inferior to Part I. The scene which precedes Dr. Corsi's second quotation (Act 2, i), where the Student returns and proves himself very much a match for the Devil, will hold its significance for all generations of teachers and pupils. Altogether it is nearly impossible to get through a day's events without wanting to quote from *Faust* again and again. Rarely has profound wisdom been expressed in such beautiful language.—I am, etc.,

Pinner, Midd'sex. E. ELKAN.

Poliomyelitis and Social Environment

SIR,—The careful study of poliomyelitis and the social environment by Professor A. Bradford Hill and Dr. W. J. Martin (August 13, p. 357) must have had a salutary effect on a number of observers who, like myself, were of the opinion that there was a relationship between the two. No one could question their results, but at the same time they have dealt with one side of a question which would appear to have two different aspects.

To quote from their own conclusion: "According to this experience favourable mortality rates indicating the favourable social conditions of a locality need not raise fears of an unduly heavy risk when poliomyelitis becomes widespread." The possibility that poliomyelitis is related to social environment might also be considered from the point of view of incidence among social class rather than incidence in an environment which contains all social classes, and my own experience, which

I realize to be very limited, has been to associate the disease with a favourable social grading.

I find on discussion with colleagues that they also feel that there is a social class distribution in relation to poliomyelitis which is quite different from that of other infectious diseases, and I would like to suggest that a second survey to prove or disprove this contention should be conducted. Simply with the idea of stimulating interest in this direction I gathered case histories of twenty-one consecutive cases which have come under my observation and placed them into social classes according to the occupation of the principal wage earner of the family. The result was as follows: Class 1, 3 cases; Class 2, 5 cases; Class 3, 7 cases; Class 4, 4 cases; and Class 5, no cases. The remaining two were a student at a primary school training college and an infant in a county council children's home.

If the above suggestion was supported by an observation on a sample of sufficient size to permit of statistically accurate deductions being made it would provide interesting material for speculation. Apart from complex associations which might be brought forward, there is a simple fact that during the period when poliomyelitis is epidemic there is a much greater amount of travel among families with larger incomes. This in turn could be an effective factor in either of two directions. In the first place it could be an application of the conclusion reached by Ritchie Russell[1] on the effect of prolonged fatigue as a predisposing factor. In the second place it could help to explain the peculiar way in which cases occur during an epidemic. These generally start with foci in a few areas and are followed by sporadic cases in many different areas.

If more accurate social histories were taken from all cases occurring during an epidemic year and the lines of travel of the affected persons in widely separated areas in the country correlated, it might be found that the apparent sporadic occurrence of cases was to a large extent mythical, and that explosive outbreaks are occurring—the cause being disseminated by victims who are passing through a long and symptomless incubation period. This would surely present a more reasonable picture of a disease which reaches its height in the middle of a hot, dry summer and is practically unknown in January.—I am, etc.,

Brill, Bucks. V. O. B. GARTSIDE.

Streptomycin in Infantile Gastro-enteritis

SIR,—In your annotation entitled "Streptomycin in Infantile Gastro-enteritis" (August 27, p. 478) you refer to an article of ours (*Lancet*, 1948, 2, 555) and say we found "that oral streptomycin alone was effective whether or not other foci of infection were present. . . ."

In fact, our experiences were quite the reverse. In discussing case 18 we said: ". . . The recurrence of diarrhoea and vomiting was due to the parenteral infection, and this should have been recognized and treated before streptomycin was considered. In the presence of such an infection streptomycin by mouth is valueless." Again, in the summary we wrote: "The administration of streptomycin by mouth does not obviate the necessity of treating parenteral infection, which may play a part in the causation of gastro-enteritis." We consider this so important that it is worth while drawing your attention to the error in the annotation.—We are, etc.,

Vitamin E

SIR,—I have just read your account (May 28, p. 951) of the International Conference on Vitamin E held recently in New York, as well as the annotation on vitamin E in the same issue (p. 949). As the person who first noted that α-tocopherol had a definitely beneficial effect on certain types of heart disease, diabetes (independently of Butturini, whose observations antedated mine by four years), and arterial peripheral vascular lesions I might be able to contribute something to the general principles underlying the use of this vitamin in these conditions.

In the first place, it is a common error to assume that vitamin E is used in these conditions as a form of replacement therapy or to remedy a deficiency. I believe that these conditions do not result from vitamin-E deficiency and that the vitamin is used as a chemical substance (in much larger doses than are needed to raise blood levels to normal) to obtain a specific physiologic effect. This can be supported by the observation that 20 mg. per day of *d*-α-tocopherol acetate will raise the blood tocopherol level to normal (about 1 mg. per 100 ml.), whereas for a therapeutic effect in the previously mentioned conditions it is necessary to give initial doses of 200 to 600 mg. daily for several weeks. The dosage may then be reduced, but in most cases at least 200 mg. per day will be required indefinitely as a maintenance dose.

Unfortunately, all of the papers which I have read by authors who had noted no satisfactory results have failed to use the method which I have suggested. I have yet to hear from any physician who has followed this method and has been disappointed in his results. It must be noted that in patients with heart disease who require digitalis the digitalis must be continued after the vitamin E is begun, but at somewhat lower doses than ordinarily used. *I would certainly appreciate hearing* from any British physician who might try this method.—I am, etc.,

281, Oxford Street, London, Ontario. A. VOGELSANG.

Cortisone

SIR,—In 1933, while doing clinical research which sought to show the existence of a tuberculous diathesis based on over-activity of the lactogenic principle of the pituitary gland—producing what I believed was tantamount to a culture medium for the tubercle bacillus, consisting of excess releasable lipin-protein in all cells at times other than the puerperium—I decided to test the action of suprarenal gland extract as a possible pituitary depressant in this respect in a case of pulmonary tuberculosis. The suprarenal extract used was in the ordinary tablet form supplied by Burroughs Wellcome and Co.

Six days after administration had commenced, the patient, a man of 25 years and of the stoutish, smooth-skinned type, exhibited all the classical signs of rheumatic fever. The treatment was stopped, and with the introduction of salicylates all the signs of rheumatic fever disappeared within ten days. Although the use of the suprarenal extract came under suspicion as an exciting factor in this flare-up, that suspicion was not strong enough to prevent a further test. But on its readministration all the signs of rheumatic fever recurred; they again subsided quickly on its withdrawal, and without the assistance of salicylates. The conclusion had to be that a suprarenal secretion, probably in excess, could be a cause of rheumatic fever, and, for the purposes of my theorizing, that its action on the pituitary was an exciting rather than a depressing one. Further experience suggests that stilboestrol had it then been available, was the substance I was seeking for my purpose, as was suggested in my paper, "Early Pregnancy and Epitheliomata," published in the *British Medical Journal* (1924, 2, 1149). Stilboestrol will depress the pituitary.

I have always favoured a theory that the rheumatic fever and tuberculous diatheses were related in a way which could perhaps be explained graphically, as is done in the case of organic compounds by the addition or removal of side chains, and that whereas rheumatic fever and pulmonary tuberculous diatheses were dependent on a pituitary-stimulated over-supply to all cells of a basal vital food product (a lipin protein) at all times, and not confined to the female only—as at times of full mammary activity—certain forms of arthritis, on the other hand, were the result of a deficiency in this same product. It seemed, therefore, that suprarenal gland extract would be of value in cases of menopausal arthritis, and I tried it in three cases of this disease in 1937, but with only a suggestion of an improvement. It is clear now that the extract was not sufficiently refined.

I think the above facts ought to be reported, because, of course, the use of 17-hydroxy-11-dehydrocorticosterone or "cortisone" in rheumatoid arthritis appeals to me as a discovery that will bring real results, but also strongly because

my own findings suggest avenues for research into the cause of rheumatic fever as well as the treatment of tuberculosis. My efforts also seem to point to a real danger if this new substance, once it becomes available, is used anything like as empirically by medical men generally as were the sulphonamides and penicillin.—I am, etc.,

St. Annes-on-Sea, Lancs. C. W. A. EMERY.

Foreign Body in the Stomach

SIR,—The following may be of interest as suggesting a new technique in the extraction of foreign bodies from the stomach without operation. I have not come across anything in the medical press up to now embodying a similar experience.

A boy aged 9 years swallowed an aluminium and enamel bottle top about the diameter of a halfpenny or rather less. It remained in the stomach for a week in spite of efforts to coax it through the pylorus by a skilful radiologist. I therefore decided to remove it, as I feared, possibly erroneously, that it might cause symptoms of aluminium chloride poisoning. Under general anaesthesia I made a small left paramedian incision and located the foreign body in the stomach. I caught up an avascular area between two tissue forceps and isolated the area with gauze swabs. On incising the stomach and seeking the foreign body with a pair of sponge-holders I failed to locate it. I then explored the stomach from cardia to pylorus with my forefinger and again failed to locate the object. To my astonishment the pylorus was dilated to the size of a florin and patulous. On picking up the stomach wall with the tissue forceps I must have shot the foreign body through this dilated pylorus as through the neck of a sack. I then found that as soon as I had opened the abdomen my anaesthetist had given a dose of curare to give as much relaxation as possible, as I was working through a small incision. The bottle top was duly recovered by the natural route 48 hours later.

I assume that all this came about through the complete relaxation under curare, and that a similar result may possibly be achieved in other cases of the same kind without the necessity of open operation.—I am, etc.,

Plymouth. C. F. MAYNE.

Hypnosis in Treatment

SIR,—You have done the ordinary non-specialist doctor a service in publishing articles on hypnosis at this time when everybody seems to be aware of it and interested in it, gleaning information either from articles in journals or from witnessing stunt displays of hypnosis in music halls. The doubt which exists in some of our minds is concerned with the question, Is it safe?

It is agreed that the central phenomenon is that of dissociation, in which I suggest it is the higher intellectual and critical faculties which are in abeyance and suppressed. The mind is then influenced on the feeling level and to a lesser degree on the intellectual level by the hypnotist: in effect we may say that the hypnotized subject is to a great extent depersonalized.

There are many of us who believe the individual personality to be sacrosanct on philosophical, ethical, religious, or moral grounds, and we attempt in our doubtless ignorant way to support and strengthen the personalities of those anxiety-type patients who consult us, so that they can have some objective view of their difficulties and overcome them themselves with our help rather than surrendering their personalities to a hypnotist, however skilled he may be and however high his motives.

I agree that there are conditions of hysteria where hypnosis is useful and valuable, as in battle conversion hysterias. But I feel that before hypnosis becomes more widespread there should be an inquiry into its effects on the whole personality, including its potentialities, by psychologists, general practitioners, religious leaders of several denominations, and philosophers.

The last war has shown us how some individuals with the most aware and most integrated personalities were able to face and overcome the severest tribulations without depersonalizing themselves. Pain is always enhanced by fear, especially when the fear is long sustained and not attached to immediate and obvious objective reality. I believe that dissociation is effective in producing an anaesthesia of the sense of fear rather than a resolution of it; the enemy is avoided rather than defeated.

Modern medical science permits marked relief from physical pain without having to resort to hypnotism. Under hypnotism the subject is depersonalized and behaves in a manner which has little relevance to what is generally judged on empirical grounds to be objective reality and which may be to a large extent inappropriate to his situation. This is done by the voluntary surrender of the higher functions of the mind to another person, with evidence of feelings of relief from tension, or of satisfaction.

An occasional pleasing experience of this sort may easily become a routine habit, with the result that the personality never faces and overcomes a problem but becomes anaesthetic to it, and thereby is likely to be weakened by this practice in the long run. I hope that the experts will be able to reassure us.—I am, etc.,

Birmingham. K. M. HAY.

The Value of Drugs

SIR,—On glancing through "Any Questions?" (August 6, p. 345) my attention was arrested by a categorical and presumably authoritative denial of the rationale of administering vitamin A and D as a general prophylactic against infection.

While keeping an open mind on the subject, it does seem to me that the simple bald statement in reply raises an enormous question that affects the whole of medicine and could hardly be dealt with in the limited space of your columns. It is simply this: With the exception of recognized specific remedies, how many of the various mixtures and preparations in common use can be definitely shown to have a positive and beneficial effect on the patient? Many of my more cynical colleagues, I fear, would be inclined to answer that question in one word.

It does seem that when so much difficulty is experienced in assessing the therapeutic value of new methods of treatment many of the "mixtures" and "tonics" that we are forced to prescribe would show up very poorly under the searchlight of modern scientific investigation. If it were possible to know the verdict of such investigations on the value of more popular mixtures and drugs we could at least have the satisfaction of knowing that even though we deceive our patients we do not deceive ourselves.—I am, etc.,

Bristol. J. E. G. HOPE SCOTT.

Syringes

SIR,—While the doctor in a single practice must admire the care and efficiency of the syringe service described by Dr. T. G. Benjamin (July 30, p. 282), he will be unable to adapt the system economically or satisfactorily for his own use.

For nearly two years I have been using one firm's portable water-boiling syringe sterilizer. It consists of a metal case with bakelite surround. The lid, on removal, carries with it a cylindrical metal cage divided into four sections. Three sections can hold syringes (or, incidentally, small instruments). The fourth is adapted to take six needles, well protected and separated from each other. The whole is contrived so that the syringe can be selected and assembled very rapidly without the hand touching anything but the barrel. A flex with universal plug allows the sterilizer to be boiled from any average lamp or wall socket. Finally the whole fits into a small transporting case with a carrying handle.

I use two of these sterilizers: one remains at my place of work and the other comes on rounds. This last is sterilized at home. As soon as it has boiled sufficiently the lid with the cage is lifted clear and the sterilizer emptied. The remaining steam quickly dissipates and the lid and cage are replaced, leaving practically dry syringes and needles ready to be used when required. If necessary (and this is rare) the sterilizer can be refilled with water and boiled up again very quickly in the patient's home.

In the sterilizer I carry two syringes of 2 ml. and one of 5 ml. capacity, which covers almost all everyday requirements. Needles of different sizes are set up in routine positions so that the required size can be selected at once. Though this does not fulfil the ideal of the M.R.C. recommendations for dry sterilization and individual packings, it is a very good second best, and a great time-saver and convenience.

Finally, I should be interested to follow Dr. Douglas Gairdner's advice on Luer syringes (July 30, p. 282), but a supplier tells me that these are becoming increasingly difficult

to obtain and that an order for Luer-fitting needles may take six months to fulfil. I am well content with the metal-topped and glass-pistoned Record syringe.—I am, etc.,

Cambridge. A. S. PLAYFAIR.

SIR,—Dr. Douglas Gairdner (July 30, p. 282) and Mr. John Foster (August 13, p. 387) may be interested to know that hypodermic syringes with nozzles of the Luer type have already been standardized for use in this country. They form the subject of B.S.1263, which was issued in 1946. Agreement on this standard was reached by a technical committee representative of the various using, manufacturing, and other interests concerned, who felt that the Luer nozzle presented advantages over other nozzles, including the Record type.

It was realized at the time that the change over to this standard syringe could only be gradual and would take some little while. The Record type of syringe has been used extensively in the past, and in consequence it was realized that there would be a continuing demand for replacements of needles until the syringes themselves were replaced.

It is, however, somewhat disappointing that there should still be such a large demand for supplies of the Record needles, as the production of needles to fit the Luer type of syringe is thereby being prejudiced. It was confidently hoped that with the support of the Ministry of Health for the adoption of syringes with the Luer nozzle the change over would be more quickly effected, as it is obviously in the interests of all concerned that those syringes with the much more satisfactory type of nozzle should come into use as quickly as possible.

Manufacturers of needles and syringes are ready to meet all demands made on them incorporating the B.S.1263 or Luer nozzle fitting, and it now only rests with the hospitals and other users to make their contribution by adopting syringes with the Luer nozzle as soon as they can.—I am, etc.,

S. J. EVERETT,

Thornton Heath, Surrey. Chairman of B.S.I. Committee on Syringes.

Gravitational Ulcers of the Leg

SIR,—Dr. S. T. Anning (August 27, p. 458) rightly stresses the role of the deep veins in the causation of gravitational ulcer. Deep thrombosis is a factor in a far higher proportion of patients than is generally realized. I do, however, join issue with him on one most important point, when he states that the treatment of superficial varicose veins in patients with venous stasis is neither rational nor useful, and more often than not harmful.

Unfortunately this is still widely taught, but I believe it to be entirely incorrect and based on the strange misconception that the superficial varicose veins aid the circulation by acting as collateral vessels to the blocked deep veins. On the contrary, in varicose veins of the kind under consideration the blood flow in the erect position is almost invariably downwards. This can be easily demonstrated. When this is so the veins are no asset, but a liability in every way.

One is sometimes asked how in these circumstances the blood returns from the lower limb. The answer is, of course, that there are not two, but three, interconnected systems of veins. For convenience one may refer to them as the deep, the varicose, and the unnamed. With the deep veins thrombosed, and the varicose veins taking the blood the wrong way, there must be a third system to do the work. These unnamed veins are the key to the situation; they comprise veins within and between the muscles, sometimes segments and duplications of deep veins which have not been affected by the thrombosis, and such subcutaneous veins as are still competent. Most of them are small, but their total blood capacity is considerable. They carry upwards not only the blood brought to the limb by the arteries but—and this is the essential point—also that which flows back into the limb via the incompetent varicose veins. This is the basis for ligating varicose veins in cases of deep venous thrombosis. It cannot be other than beneficial if the flow in them is downwards. How beneficial it will be depends on what proportion of the load on the unnamed veins is due to the venous reflux. This is difficult to assess before operation. One has to be prepared for little obvious improvement, but in the majority of cases the improvement is striking. A complete cure in so far as the patient's symptoms and healing of the ulcer are concerned (which means that the unnamed veins are now capable of carrying the load) is exceptional. Even with the help of other treatment, especially the support which is advisable in nearly all cases, real cure is unusual. One has to face this and so has the patient.

Ligation never makes the venous stasis worse; it can and should be done regardless of the state of the deep veins. Many authors avoid committing themselves on this point. Their remarks often take the form of an injunction to use discretion in advising operation for patients with a history of thrombosis. The reader, seeking guidance, too often does not get it. Aware of the danger of oversimplification, I am convinced that the indication for ligation is simply retrograde flow of blood in the vein concerned. Theoretical considerations and observation of many cases allow of no other conclusion. Students are still burdened with various tourniquet tests to determine patency of the deep veins. These tests are of interest in that they demonstrate quite strikingly certain features of blood flow and its derangement in cases of venous block and valvular incompetence. It is often possible to locate the level of communications between deep and superficial systems, but in my experience this is usually either obvious from the pressure of a thumb at the appropriate level or still doubtful after repeated application and removal of tourniquets at different levels. While not denying the occasional clinical usefulness of tourniquet tests when simpler methods fail, I suggest that their practical value is small and that their real place is in the applied physiology class.

Dr. Anning mentions having seen disastrous results of treating superficial varices in several patients. There are two explanations. First, this is a progressive disease; both extension of thrombosis and recanalization of blocked deep veins may worsen the venous stasis. Secondly, I suspect that those patients who have been notably worse soon after treatment have had their varices injected as well as, or instead of, ligated. The risk of sclerosants causing further deep thrombosis must be small, since many surgeons of experience have employed them in these cases for years, but I believe the method to be unsound and that it should not be used for patients who have or have had deep thrombosis.

That ligation of superficial varicose veins is by no means the whole answer to gravitational ulcer is obvious, but it is a valuable method of treatment, and it does in fact have a rational basis. The veins are derelict. Their contribution to the circulation is one of sabotage, hampering the work of such veins as are still endeavouring to maintain the circulation.—I am, etc.,

Bristol. H. J. CROOT.

SIR,—Dr. S. T. Anning (August 27, p. 458) has performed a valuable service in dispelling some of the mist which obscures our understanding of ulceration of the legs. His main conclusion will bear restatement: so-called varicose ulcers are not the result of varicose veins. A long experience of the cases seen in a varicose-vein clinic has convinced me of the truth of this after having observed: (1) that the great majority of leg ulcers occur in patients who either have no varicose veins or have varicosities which from their small size or number or by their remote situation cannot be regarded as the cause of the ulcers; (2) that vast numbers of people with varicose veins of long standing and of every degree of severity never develop ulcers.

Recognition of these simple facts suggests one immediate line of progress—to abandon the term "varicose ulcer." This in itself would do much to promote a more rational approach to the whole problem. What name should we use in its place? Dickson Wright's term "gravitational ulcer" goes straight to fundamentals in so far as the elimination of the effect of gravity is the most potent single factor in curing these ulcers. It is, however, insufficiently comprehensive to cover the syndrome which, besides ulceration, may include oedema, induration, and eczema, and whose most distressing symptom is pain. Bauer's term, "lower leg syndrome," acknowledges the multiplicity of the manifestations of the malady, but it is cumbersome and omits reference to the effect of gravity. "Gravitational syndrome" suggests itself as an improvement.

Concerning aetiology, the emphasis in Dr. Anning's paper is upon a pre-existing thrombosis of the deep veins of the leg and thigh. In questioning my own patients, however, I have been puzzled by my frequent failures to obtain a history of "white leg" or other thrombotic manifestation. For a time convinced as I was that the fault lay in the deep veins, I thought that a "silent" thrombosis must have been the cause in the majority of these cases of gravitational syndrome. I have sought confirmation of this by phlebography, surgical exploration, and biopsy.

Bauer[1] has pointed out that for this purpose injection of the contrast medium into the small saphenous vein behind the external malleolus is of little value. Not only is the filling of the deep veins very uncertain by this method, but, since the contrast medium follows the normal direction of flow of the venous blood, an identical appearance is given by a patent femoral vein whether or not the valves are competent. These objections are overcome by using Bauer's method of retrograde injection. The patient is tilted feet down at an angle of 45° and the injection is made into the upper end of the femoral vein. The radio-opaque substance flows down the vein by gravity.

If the vein is normal the medium is held up by the first valve an inch or two below the point of injection, and below this the radiograph shows no shadow or only a very faint one. If the vein has deficient valves the medium immediately drops along the whole length of the femoral and popliteal veins into the deep veins of the leg. The cusps of the valves are usually visible, indicating that they are functionally incompetent but neither congenitally absent nor destroyed by disease. If the vein has been previously thrombosed and recanalized a narrow, irregular channel replaces the normal broad, smooth appearance, or a leash of fine satellite vessels derived from the adventitia is substituted for it. No trace of valves is visible.

In the cases of gravitational syndrome which I have investigated by retrograde phlebography I have been struck by the preponderance of femoral veins of wide calibre and smooth outline showing total or partial incompetence of the valves. Surgical exploration of these veins has revealed no periphlebitis. Microscopical examination of pieces excised shows either a normal appearance or varying degrees of fibrosis of the media with degeneration of the intima but no evidence of thrombosis.

It seems, therefore, that the statement made by these patients that they have had no previous thrombosis is true, confirmed as it is by phlebography, surgical exploration, and histological examination. Bauer has called these cases of gravitational syndrome "idiopathic," and the cause of the dilatation and valvular incompetence of the deep veins may be a combination of wear and tear, hereditary weakness, and such metabolic disorders as those at which you hint in your annotation (p. 480).

As regards treatment, we know that practically all gravitational ulcers can be healed by sufficiently prolonged recumbency and many by the continuous support of suitable bandages. The problem suggested by the foregoing observations is whether this slow process of healing can be appreciably hastened by permanent interruption of the femoral or popliteal vein to remove the hydrostatic pressure of the contained column of blood from the vessels of the lower part of the leg. It is certain that the indiscriminate performance of the operation of high saphenous ligature is not the right treatment of gravitational syndrome.

Dr. Anning is to be congratulated on giving an impulse to the critical examination of the question of what may be achieved by surgical attack on the deep veins.—I am, etc.,

FRANK FORTY.

Edgware, Middlesex.

Amoebiasis in England

SIR,—I was very interested to read somewhat belatedly the article by Drs. A. R. D. Adams and D. R. Seaton (July 16, p. 136) referring to amoebiasis in England. Had the cases occurred in, say, Rugby or Cambridge they would, I think, have been of more interest, but occurring in Liverpool they are surely not unexpected. Liverpool is a seaport and has a floating population of seamen, including Lascars and Indonesians who come from places where the cyst-carrier rate is high. They also do not share our own ideas of hygiene. Apart from the ship's officer and the doubtful infection by the father who was born in India (though a case has occurred in Australia, where amoebic dysentery is non-existent, of a relapse 20 years after contraction in Gallipoli, and which, incidentally, went on to liver abscess) some surprise seems to be voiced on the occurrence. One of the families contained a docker, and it is not unreasonable to suppose that all had contacts with dockside folk, and, as has been pointed out, they were all from unhygienic surroundings.

I must also take exception to the term "acute" amoebic dysentery. Amoebic dysentery, as seen by the vast majority of Service and colonial doctors, is a chronic or, at worst, a sub-chronic disease, in that if untreated or incompletely treated it takes many years to kill, if at all—the majority of cases clearing up and becoming cyst carriers. Even Manson-Bahr only admits to seeing a "few cases only" of acute amoebic dysentery. It has been left to workers in Java and on the Burma-Siam "railway of death" to see the real acute amoebic dysentery. These cases pass up to 40 to 50 stools per day and die in about 10 to 14 days, if untreated, in great agony—conscious to the last, with vomiting and maniacal symptoms.[1] —I am, etc.,

Memorial to Charles John Bond

SIR,—It has been decided in Leicester to raise a fund for a memorial to the late Charles John Bond, C.M.G., F.R.C.S., and it is thought that there may be friends of his elsewhere who would like to know about this project and be given an opportunity of showing their appreciation.

Bond was born in Leicestershire in 1856, and after his training at University College Hospital, London, he returned to live and work in Leicester until his death in 1939. He was pre-eminently a scientist, and his publications, which are very many and of great interest, show his surgery to have been far ahead of his time. His work was done in the Leicester Royal Infirmary, but also, as was the custom in those days, often in the patient's home in the country under very simple conditions. In an exceedingly busy life he never ceased from original and experimental research. This he did in a wide range of subjects which brought him international recognition. He began with two papers on anatomy as a student, passing in turn to surgery, gynaecology, haematology, and genetics. The breeding experiments in birds and plants were carried out in his own garden. For 40 years he was the close friend of the late Sir Victor Horsley, F.R.S., and Bond showed in his book *Recollections of Student Life and Later Years* how closely their work was integrated.

During the 1914–18 war he was gazetted honorary colonel in the Army Medical Service and became consulting surgeon (with the late Lord Moynihan) to the Northern Command. He was a member of the Medical Research Council of the Privy Council, and he represented the Medical Research Council on the Inter-Allied Commission on Treatment of War Wounds held in Paris from 1916 to 1918. During these years he studied wounds, immunity, the effect of antiseptics on body tissues, and leucocyte activity, finding time to publish his own observations: these are of particular interest to read in relation to the work done in these subjects in the second world war 25 years later. Throughout his work, in all its ramifications, he correlated his wide experience and philosophy with the sociological problems of the times. Were he alive to-day he would undoubtedly have been keenly interested in the State Service which he foresaw as early as 1912. Nothing was too big to daunt him nor too trivial to be ignored. He observed, recorded, and deduced with courage, but there was a characteristic humility and consideration for the opinions of others.

Surely it must be unique for a surgeon to have carried out so much valuable work on so many subjects, based on a sound pathological foundation, unattached to any of the great teaching hospitals. Bond decided to work in the provinces, where, it is true, the material is always abundant and good but where there was no medical school, and for many of the earlier years of his life there was no laboratory accommodation. It seems fitting that such a life should be commemorated for our inspiration.

It is proposed to place a plaque in the Leicester Royal Infirmary and also to create a fund to enable students in biology at the Leicester University College to have greater opportunities for research and travel. Any contribution to this memorial should be sent to the Honorary Treasurer, Dr. L. K. Harrison, 2, Springfield Road, Leicester.—We are, etc.,

Leicester.

Family Planning

SIR,—I receive literature from the Family Planning Association in which the following adequate reasons for family limitation are recognized: (*a*) too many children already (6 to 15); (*b*) "younger married women who are determined not to be driven into the slums, as their parents were driven, by the birth of a child year after year, on an income hopelessly inadequate to support them."

For many years now I have been dealing in my practice with women of all ages and economic groups who are led to seek my advice on contraception. My yardstick is this: Here we have a woman of child-bearing age who prefers not to conceive. She is recognized by the laws of this country as being a fit and proper person to vote at any election, to be conscribed for military purposes, to sit in the Lower House, to become a magistrate, and, in general, to be entitled to sex equality. I do not inquire into the particular personal reason the woman may have in seeking my advice. Subject to whatever interpretation one may feel inclined to put upon the marriage vows, and given always the husband's approval, I inquire no further. From that point on I consider that my position is purely that of technical adviser. Am I wrong?—I am, etc.,

Worthing. O. P. CLARK.

The Osler Family

SIR,—I am glad I wrote (July 9, p. 45) that Edward Osler's well-known hymn is *almost* the sole survivor of many; for in the same issue (*Supplement*, p. 40) in the account of the official religious service at Harrogate a much better-known hymn, "Praise the Lord, ye heavens adore Him," is ascribed to him under the disguise of "Ostler." The two authentic verses of that hymn are anonymous, but derived from the Foundling Hospital's eighteenth-century collection, and to that extent medical. In some books—e.g., the *English Hymnal*, 1906, Oxford, number 535—a third verse, by Edward Osler, is added. In some other books it is entered as a separate hymn: it begins, "Worship, honour, glory, blessing, Lord, we offer to thy name."

The name, which a Greek scholar once fancifully derived from *Oiseleur* (fowler), is, of course, the same as Ostler, though William Osler's family pronounce the *o* long, like "owe-slur." The word has descended in the scale of respectability. In the thirteenth century, when names became hereditary, it meant a hosteler, from *hospitalarius*, appropriately having to do with guests.—I am, etc.,

Montreal. W. W. FRANCIS.

POINTS FROM LETTERS

Percussion Finger

Dr. Z. P. FERNAND (Leeds) writes: Dr. A. Niven Robertson's personal note on "percussion finger" (August 20, p. 440) interested me, apart from his being one of the pioneer municipal tuberculosis clinicians of the period following the 1914–18 war. In 1925, as chief clinical T.O., Leeds (population 500,000, with the highest known notification of 1,709 tuberculosis cases), a prominent "hoof," as my staff then styled it, was found on the dorsum of the terminal phalanx of my middle finger, nearer the proximal end. The swelling was not painful but very noticeable and distinctly palpable. Though I left municipal service two years later, the nodule is still palpable though not so noticeable.

Reform in Medical Education

Dr. H. M. FLANAGAN (Lincoln) writes: There is a tendency nowadays among some to lean more and more on the usually overworked laboratory at the expense of clinical methods. The trend towards the ultra-mechanistic approach to the human organism, in a rashly enthusiastic effort to force the invaluable scientific method in medicine, is one which will ultimately lead to more confusion and final sterility. In medical education one commences with an interest in sick people, but is invited to begin with molecules and atoms. Perhaps to start with medicine and work back through anatomy and physiology to chemistry and physics is impractical, but it is the natural process of the inquiring mind, confronted with a complaining patient, to work back to understand his disorder in terms of fundamentals like biochemistry. It would tend to follow the history of medicine and so keep the student's interest at a similar high level to that of medical pioneers down the centuries.

Obituary

F. HERNAMAN-JOHNSON, M.D., F.F.R.

With the death of Dr. Francis Hernaman-Johnson at the age of 70, on September 3, British radiology has lost another of the few remaining pioneers in this branch of medicine. Dr. Hernaman-Johnson was physician to the Charterhouse Rheumatism Clinic for many years and chairman of the council of the British Rheumatic Association.

Francis Hernaman-Johnson was born at Crosby, Lancashire, and was educated at the Merchant Taylors' School there. He went on to study medicine at Aberdeen University, where he graduated M.B., Ch.B. with honours in 1904, proceeding M.D. in 1910. He obtained the Cambridge D.M.R.E. in 1931, and in 1939 was a foundation fellow of the Faculty of Radiologists. As a student he won many prizes and honours, including a Liddell bursarship, the first medal for advanced physiology in 1902, and the Duthie scholarship a year later.

Part of his clinical training was undertaken at St. Bartholomew's Hospital, and after graduating he joined the Royal Navy, serving for three years, some part of which he spent at the Royal Naval Hospital, Plymouth. On leaving the Navy, Hernaman-Johnson went into practice at Bishop Auckland, Durham. At that time he was interested in electrotherapy, and it was almost inevitable that he should be attracted to the growing field of radiological work, a part-time activity expected of many electrotherapists in those early days. Soon he was appointed consultant radiologist to the Darlington Education Committee. During the 1914–18 war he was attached to the Cambridge Hospital, Aldershot, and was consulting radiologist and electrotherapist to the Aldershot Command, being mentioned in dispatches for his services. After the war he settled in London.

Dr. Hernaman-Johnson was consulting radiologist to the French Hospital, and he was on the honorary staff of the Croydon General Hospital, the Margaret Street Hospital for Diseases of the Chest, and the Carshalton Memorial Hospital. He had been a member of the Roentgen Society since 1911 and was a member of the council in 1926. He was president of the Section of Radiology of the Royal Society of Medicine in 1934–5, and was the first Warden of the recently formed Faculty of Radiologists. He was also the first Skinner Lecturer of the Faculty.

Right from the early days Dr. Hernaman-Johnson took a great interest in the use of *x* rays in therapy and especially in the treatment of rheumatism. This interest continued throughout his life, and he contributed numerous papers to this and other journals on such subjects as the value of *x* rays in chronic arthritis, constitutional effects of *x* rays, the relative values of *x* rays and radium, and on radiotherapy from many other aspects.

Dr. Hernaman-Johnson was an expert and thorough worker, always anxious for the progress and advancement of his specialty. He never spared himself, and he inspired confidence in his patients and his colleagues. In recent years he had devoted much of his time and energy to the British Rheumatic Association. He was active in promoting schemes for occupational therapy and rehabilitation and for providing homes where patients could rest in between courses of treatment. He brought the same keen interest to his work for the Scientific Advisory Committee of the Empire Rheumatism Council.

One other facet of Hernaman-Johnson's many activities should also be recorded. Using the pseudonym "Francis Wimbrook," he wrote a number of articles for the lay press, and a "psychological thriller" called *Accident* which was staged at the Richmond Theatre. A novel, *Behold the Axe!* was published only last year.—R.J.R.

H. LESLIE-ROBERTS, M.D.

Dr. Hugh Leslie-Roberts, who died on September 8 at his home in Heswall, Cheshire, at the age of 89, was formerly consulting physician to the skin department of the Liverpool Royal Infirmary. He retired from practice in 1938, and his wife, who was the daughter of Mr. Samuel Parker, died only a few weeks ago.

Hugh Leslie-Roberts, the son of Alderman J. F. Roberts, of Manchester, was born in 1860 and began his education at Owens College, Manchester. Subsequently he studied in Edinburgh, where he graduated M.B., C.M. in 1887, proceeding M.D. in 1893. He also spent some time on post-graduate studies in Hamburg and Berlin, and in Paris and Vienna. It was in 1890 that he settled in Liverpool, and three years later he was appointed to the staff of the Liverpool Royal Infirmary. For many years he was lecturer on diseases of the skin at Liverpool University, and apart from his contributions to the medical press he published a treatise on mould fungi parasitic on man. As early as 1894 he was secretary of the Section of Dermatology at the annual meeting of the B.M.A. He was vice-president of the Section in 1904 and 1912 and president in 1922.

Dr. ARTHUR CECIL HINCKS died in the Wells Cottage Hospital on August 26 after a long period of ill-health. He was born at Hay, Hereford, in 1882, and was educated at Christ Church College, Brecon, and Birmingham University, where he played in the rugby fifteen and was captain of the hockey eleven. He graduated M.B., Ch.B. in 1906, and after holding resident appointments at the General Hospital, Birmingham, he came to Wells in 1909 as a partner of Dr. Allan and Dr. Lauder Smith. At the outbreak of the 1914–18 war Dr. Hincks joined the 4th Somersets, but before they left for India he was transferred to the 26th Field Ambulance and went to France with the Expeditionary Force. For conspicuous gallantry and devotion to duty he was awarded the Military Cross in 1915. In the recent war he served as a major in the local Home Guard and was also an A.R.P. lecturer and instructor. He took an active part in the work of the British Legion and had been president of the local branch. For many years Dr. Hincks had been medical officer of health for the city of Wells and senior physician at the cottage hospital. He was a keen churchman and had held office as sidesman and churchwarden. Despite all these and many other interests he found time to serve his colleagues on the local medical and panel committee and on the Somerset Insurance Committee. He was chairman of the East Somerset Division of the British Medical Association in 1932–3; a representative on the Branch Council from 1934–48; representative of the Division in the representative body in 1941 and from 1943–48, when he resigned on account of ill-health. He was also a member of the Local Medical War Committee from its inception. With his passing the people of Wells have lost a family doctor who will ever be remembered with respect and affection by all those with whom he came in contact. To Mrs. Hincks and the members of his family the deepest sympathy is extended by all his colleagues. —G.E.M.

Mr. HARRY VERNON WELLS died on September 2 at Sanderstead, Surrey, at the age of 49. A student at Charing Cross Hospital, he graduated M.B., B.S. in 1926 and went on to take the F.R.C.S. three years later. He was resident casualty officer and later surgical registrar at his teaching hospital.

J.B.S. writes: I must express the heartfelt sorrow his partners and patients feel. It is safe to say there was no man more loved by those who knew him. Wells had been in Sanderstead for seventeen years. He came here with an established reputation, both from Charing Cross, where his chiefs could not speak highly enough of him, and from Birmingham, where he worked for some years. When he joined me in practice here I could see at once what a marvellous technique he had, especially in abdominal surgery. His cases, of course, included every branch of general surgery. There were a number which I referred to him quite hopelessly, but his technique and optimism triumphed over and over again. I have never met a better man: he was uniformly courteous, always sincere and kind. That is not to say he was not firm, even obstinate, about some things, but he always knew his own mind. In the long years of our friendship he never once failed my partner and myself in any difficulty, and we shall miss him greatly.

He volunteered for service in the Army or Air Force at the beginning of the war and again later on, but he was refused by the medical board. He was very troubled about this, and wrote to the president of one of the boards complaining that somebody must have misunderstood his condition, as he felt in perfect health and was quite able to undertake any effort. A very kind letter from the president of the board comforted him, but he was assured that he would not be accepted. However, surgical work in connexion with Purley Hospital was quite sufficient to give him far more to do than he ought to have done. There were very few surgeons left in this district, and there was hardly a night when Wells was allowed to sleep in peace during the war years. He was sent for in every important emergency and for most major operations. I think it sad that no public acknowledgment has been made of his services so freely and unselfishly given, though his friends let him see how much they valued him and his work. I want to express everybody's sympathy with his wife, Dr. Mary Wells, in her loneliness and bereavement.

Medico-Legal

BREACH OF TERMS OF SERVICE

N.H.S. Patient Charged a Fee

A report from the Medical Service Committee which was adopted by the Executive Council for the County of Surrey on March 9 gave the findings of the committee in three cases of complaints against doctors. One was dismissed as frivolous, on another no action was recommended, and in the third case the doctor was held to be at fault.

In this instance the complainant's written statement alleged failure on the part of the doctor to comply with the terms of service in that he (*a*) made a perfunctory examination; (*b*) uttered remarks to which the complainant took exception; (*c*) in issuing a medical certificate used an incorrect form for the purpose; (*d*) demanded and accepted a fee of five shillings; and (*e*) ordered drugs required for treatment on a form other than that supplied by the council. In the view of the committee the following facts were established. The complainant was accepted by the doctor for inclusion in his list, and on several occasions before this complaint was made the complainant had received treatment as a registered patient. On September 23, 1948, the doctor carried out an abdominal examination of the patient and took his temperature. During the course of this visit the doctor made observations inconsistent with the dignity of his profession. He then ordered the drugs needed on a form other than that provided by the council, and he issued a private certificate. The doctor then demanded and accepted a fee of five shillings in respect of his treatment of the patient.

On October 18 the patient wrote a letter asking for a receipt for the five shillings which had been paid. On October 19 the doctor issued a receipt on a form provided by the council in respect of treatment given under Paragraph 5 (2) of the First Schedule to the National Health Service (General Medical and Pharmaceutical Services) Regulations, 1948.

The committee agreed that certain inferences might properly be drawn from these facts. (1) The doctor was aware that he

had accepted the complainant for inclusion in his list. (2) The doctor carried out a satisfactory examination and ordered such drugs as he considered necessary. (3) The doctor failed to comply with the terms of service, however, in that he ordered drugs for the treatment of the complainant on a form other than that provided by the council, and in that he demanded and accepted a fee in respect of the treatment given.

The committee therefore recommended that the council should recover from the doctor, by a deduction from his remuneration, expenses incurred by the complainant owing to the failure of the doctor to comply with the terms of service, and that the council should make representations to the Minister of Health that, owing to the failure of the doctor to comply with the terms of service, the sum of ten pounds should be withheld from his remuneration.

Universities and Colleges

UNIVERSITY OF BIRMINGHAM

Humphrey Francis Humphreys, M.B., Ch.B., M.D.S., F.D.S. R.C.S., Professor of Dental Surgery in the University, has been appointed Vice-Principal of the University from September 30 in succession to Professor M. L. E. Oliphant, F.R.S., Poynting Professor of Physics.

SOCIETY OF APOTHECARIES OF LONDON

Professor E. C. Dodds, F.R.S., Master, presided at recent meetings of the Court of Assistants, at which Mr. Duncan C. L. Fitzwilliams was elected Master from August 24 and Dr. Frank Howitt and Dr. G. Roche Lynch were elected Wardens.

The report of the sudden death through an accident of Dr. Christopher Thackray Parsons, Past Master, was received with regret.

John Francis Carter-Braine took his seat upon the Court of Assistants.

The following appointments were made: Mr. L. Vernon Cargill to the Chelsea Physic Garden Committee of Management for a further four years from August 20; Professor Dodds to the Ministry of Health Joint Committee in connexion with Part IV of the National Health Service Act; Sir Cecil Wakeley to the British Postgraduate Medical Federation for a further year from October 1.

Mrs. Cecil Wall presented a large collection of manuscripts by the late Dr. Cecil Wall, Archivist, on the history of the society and its hall.

The following were granted the Diploma in Industrial Health upon examination: J. A. Herd, C. N. D. Cruickshank, C. Crowley, G. G. Mathew, W. G. White.

The Diploma, L.M.S.S.A., was granted upon examination to the following: H. T. H. Beach, J. L. Jarvis, D. Redpath, G. E. Hanks, F. W. Retief, M. P. Cardew, K. C. Horrocks, E. M. Tiger, H. V. White, M. P. M. Coupland, R. J. Aspinall, C. J. G. Menzies, C. R. May, M. C. H. Jackson, H. E. G. Dyer, F. Walton, F. E. Bramwell, E. R. Goodall, D. J. Joubert, G. B. Stephenson, W. G. Burvill Holmes, G. T. Cecil, G. A. R. Giri, P B. Poole, A. K. Kantarjian, L. Kader, J. D. Morris, C. T. Jones, E. W. Melia, M. C. Gilbert, A. S. Murad.

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS

The William Meredith Fletcher Shaw Memorial Lecture will be delivered by Professor R. W. Johnstone, C.B.E., M.D., F.R.C.S.Ed., F.R.C.O.G., at the College, 58, Queen Anne Street, London, W., on Wednesday, October 12, at 2.30 p.m. His subject is: "Scotland's Contribution to the Progress of Midwifery in the Eighteenth and Early Nineteenth Centuries." An invitation is extended to doctors interested in the subject, but admission is by ticket only, obtainable from the secretary.

The Services

The announcement of the award of the Efficiency Medal (Territorial) to Captain (now Temporary Lieutenant-Colonel) A. B. Dick, R.A.M.C., in the *London Gazette* of May 2, 1947, and printed in the *Journal* of May 31, 1947 (p. 789), is deleted in a list of errata published in a *Supplement* to the *London Gazette* dated August 12, 1949.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended August 27. [No. 34

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The *16 principal towns in Scotland*. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

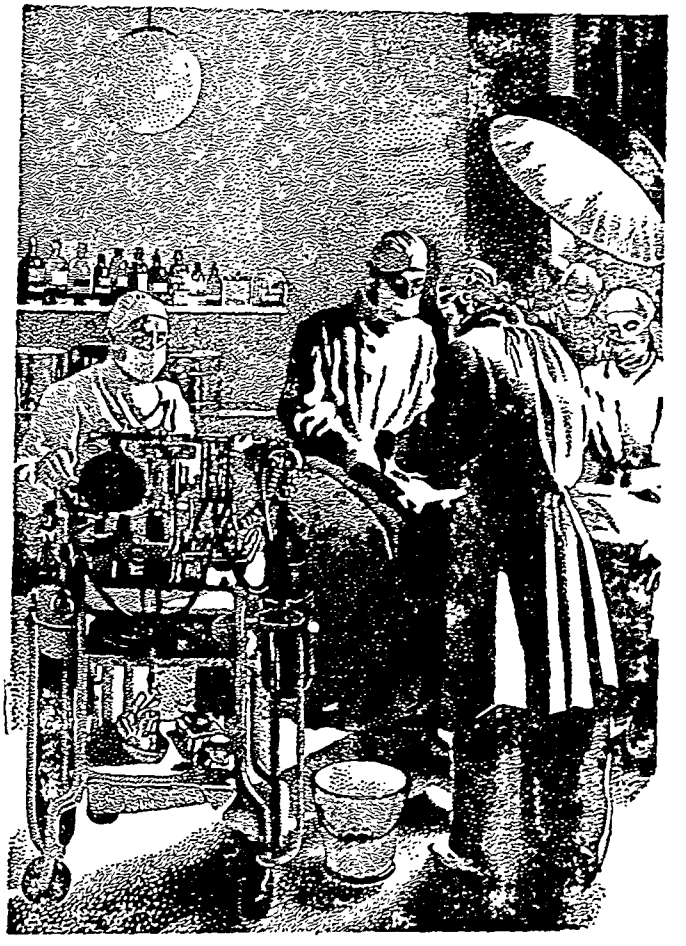
Rate per 1,000 total births (including stillborn)			37					32		

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.



† Deaths from measles and scarlet fever for England and Wales, London (*administrative county*), will no longer be published.

‡ Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

§ The number of deaths from poliomyelitis and polio-encephalitis for England and Wales, London (administrative county), are combined.

‖ Includes puerperal fever for England and Wales and Eire.

ANAESTHETICS

'TRILENE'–in addition to its use in analgesia–is employed with success for the production of a light plane of anaesthesia. Contra-indications are few, and recovery is rapid with no unpleasant after-effects.

Containers of 250 and 500 c.c. Crushable ampoules of 1 c.c. in boxes of 5; ampoules of 6 c.c., boxes of 1, 5 and 25.

'KEMITHAL' SODIUM is a highly efficient ultra-short-acting barbiturate used for induction and surgical anaesthesia of short or prolonged duration. Notable features of its use are minimal respiratory depression and a consistently good post-operative recovery, free from vomiting, restlessness and protracted depression.

Ampoules of 1 or 2 grammes, with or without distilled water. Containers of 5 and 25.

Other anaesthetics and analgesics include: 'Avlon' brand Chloroform, Procaine, and Pethidine (with and without Hyoscine).

ELIXIR METHADON

(preparation of dl-2-dimethylamino 4 : 4 diphenylheptane-5-one hydrochloride)

ELIXIR METHADON (SMITH) is a palatable preparation containing as its active ingredient 2.5 mgm. per fluid drachm of Methadon, the high potency synthetic analgesic. Methadon has proved effective in relieving a wide variety of painful conditions and administration as elixir has definite advantages.

DESCRIPTIVE LEAFLET ON REQUEST

Elixir Methadon (Smith) is available in 4-oz. and 16-oz. bottles and is exempt from purchase tax. It is within the regulations of the Dangerous Drugs Acts.

Fundamentals

PEPSIN AND ACID, although not the ultimate cause of peptic ulcer, prevent its healing and make possible its continuance and recurrence. The fundamental factor is, therefore, to control the action of pepsin in a highly acid medium and create an environment which permits the ulcer to heal.

'ALUDROX' therapy neutralises excess acid and partially inactivates pepsin, leaving the stomach in a sufficiently acid condition to allow normal protein digestion. 'ALUDROX' promptly relieves pain and in conjunction with a bland diet and rest ensures rapid healing of the ulcer.

'ALUDROX' is available in two forms: a suspension of 5.6% colloidal aluminium hydroxide in gel form, in 6 oz. and 12 oz. bottles, and as 10 gr. tablets in boxes of 60 tablets.

'Aludrox' *Aluminium hydroxide gel*

EPIDEMIOLOGICAL NOTES

Food-poisoning at Llanelly

The recent outbreak of food-poisoning at Llanelly due to *Salmonella typhi-murium B* started explosively on August 15, when 62 cases were notified, and rapidly tailed off within a week, although some cases from secondary "cropping" have been notified since. Altogether 214 cases have been notified, and of these 142 were seen in the first three days.

The source of the infection was a large tin of artificial cream at a pastry shop, where five carriers were discovered; the cream was being used "cold" in the finishing of the pastries. In the course of the investigation five carriers were also discovered in an ice-cream shop, but no contamination of the ice-cream appears to have occurred. The source of infection of the carriers themselves is problematical, sporadic cases of the disease having occurred in the area since the large outbreak at Ammanford three years ago, which was traced to a butcher's assistant infecting cold made-up meats. This butcher's assistant, from the evidence available, appeared to have been infected originally by eating unwashed imported fruit.

The infection was generally mild. The presenting symptoms were diarrhoea and vomiting, which usually came on within 24 hours and only exceptionally lasted longer than three days. Of the 12 cases admitted to hospital only three were seriously ill; an old lady of 80, a young man of 20, and a baby who had a congenital defect. Chloromycetin appeared to have a beneficial effect on these three cases. A man of 63 who was also affected died in hospital from coronary thrombosis a week after admission. Post-mortem examination revealed no trace of the *Salmonella* infection, and confirmed the recent coronary thrombosis with widespread arteriosclerosis and myocardial degenerative changes.

Poliomyelitis

Notifications in England and Wales for the week ended September 3 were poliomyelitis 289 (258), polio-encephalitis 19 (22). Figures for the previous week are shown in parentheses.

The fluctuation during the past three weeks is not considered to have any special significance. The rise to 308 notifications since the last report should not be taken as indicating the likelihood of any further rises of considerable magnitude.

The multiple cases in counties were as follows: London 43 (34), Berkshire 5 (3), Chester 3 (0), Cornwall 5 (5), Cumberland 1 (1), Derby 2 (2), Devon 7 (4), Dorset 2 (2), Durham 8 (3), Essex 21 (13), Gloucester 13 (14), Hertford 3 (6), Huntingdon 2 (0), Kent 10 (9), Lancaster 28 (33), Leicester 11 (1), Lincolnshire, Kesteven 2 (0), Lincolnshire, Lindsey 5 (3), Middlesex 18 (17), Northampton 3 (4), Northumberland 10 (6), Nottingham 6 (7), Somerset 9 (6), Southampton 10 (16), Stafford 3 (4), Suffolk East 2 (1), Surrey 7 (5), Sussex East 2 (5), Sussex West 3 (2), Warwick 8 (7), Wiltshire 4 (3), Worcester 4 (0), Yorkshire West Riding 37 (33), Glamorgan 5 (1).

Discussion of Table

In *England and Wales* there was a decrease in the notifications of measles 342 and acute poliomyelitis 15. Increases were recorded in the incidence of dysentery 55, scarlet fever 40, and whooping-cough 34.

A decreased incidence of measles was recorded in practically all areas; the largest falls were Kent 62, Middlesex 45, Lancashire 44, and Yorkshire West Riding 44. The only notable exceptions to the general trend for measles were increases in the notifications in Durham 52 and in the rural district of Cambridgeshire 37. There were no large changes in the local returns of scarlet fever.

The largest fluctuation in the incidence of whooping-cough was a rise of 36 in Durham. Notifications of diphtheria were 7 below the record low level of last week.

The rise in the incidence of dysentery was due to two outbreaks, one affecting 29 persons in Staffordshire, Wolverhampton C.B., and the other with 25 notifications in Monmouthshire, Rhymney U.D. There were 9 cases of paratyphoid fever in Lancashire. The largest number of notifications of food-poisoning was in Carmarthenshire, Llanelly M.B. 22 (see above).

In *Scotland* there were falls in the notifications of acute primary pneumonia 53 and dysentery 15 and rises in the incidence of whooping-cough 25 and measles 18. In Glasgow 46 of the 68 cases of dysentery were notified. There was also an increase of 9 in the notifications of cerebrospinal fever in Glasgow.

In *Eire* decreases were recorded in the notifications of whooping-cough 49, measles 28, and scarlet fever 21, while the incidence of diarrhoea and enteritis rose by 12. Of the 74 cases of diarrhoea and enteritis 62 were notified in Dublin C.B.

In *Northern Ireland* the notifications of scarlet fever increased by 16, while a fall of 10 was recorded in the incidence of whooping-cough. The rise in the notifications of scarlet fever was due to the experience of Belfast C.B.

Week Ending September 3

Notifications of infectious diseases in England and Wales during the week included: scarlet fever 701, whooping-cough 1,615, diphtheria 53, measles 1,168, acute pneumonia 216, cerebrospinal fever 25, acute poliomyelitis 289, acute polio-encephalitis 19, dysentery 98, paratyphoid fever 30, typhoid fever 9, food-poisoning 277.

Medical News

Oliver Memorial Fund

The committee of this fund has made the second award for service in connexion with blood transfusion to Dr. H. F. Brewer, clinical pathologist to St. Bartholomew's Hospital. Dr. Brewer has been medical officer to the British Red Cross London Blood Transfusion Service for 16 years, and has been intimately connected with the development of this pioneer service. His attention to the welfare of the donor has engendered a spirit of confidence among the members, and data obtained from the periodic examination of donors after multiple bleedings established the safe minimum intervals between donations for males and females. In the years immediately before the war the Red Cross Service made the first provision for the distribution of reliable and cheap anti-A and anti-B grouping sera, and Dr. Brewer played a significant part in ensuring this. His influence was continued throughout the war as director of one of the London blood supply depots.

Association des Médecins de Langue Française

The *Association des Médecins de Langue Française* was founded in 1911 to facilitate contacts between French-speaking doctors in different countries. The association arranges conferences in French-speaking countries to bring members together for discussion of various medical questions. Between the two wars the association had several hundred members in France and in other countries, and a conference was held every other year. Since the end of the war one meeting took place in Paris in 1947, and a second is planned for this October in Geneva. New members will be cordially welcomed, and the secretary, Professor Cade, would greatly appreciate information about changes of address from former members, particularly from those living outside France. The registered office of the association is at the Faculty of Medicine of Lyons, and all details about membership can be obtained from Professor A. Cade, 10, rue de la Charité, Lyon, Rhône.

Wills

Dr. Charles William Menelaus Hope, formerly consulting surgeon for diseases of the ear, nose, and throat to King's College Hospital, left £39,375. After making a number of bequests he left the residue of his estate as to one-third to King's College Hospital, and two-thirds to King's College Hospital Medical School. Dr. Henry Wilkes Gibson, of Emsworth, Hants, left £32,538; Dr. William Gordon Alexander, of Broadway, Worcs, left £6,008; Dr. Harold Godfrey Young, of Hatfield, Herts, left £7,492; and Dr. John Donald Matheson MacKellar, of Dewsbury, Yorks, left £10,165.

COMING EVENTS

British Rheumatic Association Exhibition and Conference

The British Rheumatic Association has arranged a two-day conference to be held at Chelsea Town Hall, London, S.W., on Wednesday and Thursday, September 28 and 29. The opening address, on "Modern Views on the Treatment of Rheumatoid Arthritis," will be delivered on September 28, at 2.30 p.m., by Dr. W. S. C. Copeman, and at 5 p.m. Dr. W. S. Tegner will discuss "The Care of the Rural Patient." On September 29, at 2.30 p.m., addresses will be given by Miss Nora Hill, Principal of the Disablement Branch of the Ministry of Labour, and Air Commodore G. O. Venn, Executive Director of "Remploy," Ltd., and at 5 p.m. there will be a symposium on "The Home-bound Employed," in which the special problems of rheumatic patients will be presented from the points of view of the doctor, the industrialist, and the patient by Dr. Francis Bach, Mr. Sydney Arthur, and Miss B. M. Stow, Chairman of the Association of Occupational Therapists, respectively. Tickets for the conference (price 10s. each) will be allocated in order of application. The association has also arranged an exhibition to be held on September 27 (2 p.m. to 10 p.m.), September 28 and 29 (10 a.m. to 10 p.m.), and September 30 (10 a.m. to 6 p.m.), which will be open to the public (entrance fee 1s.). Full particulars may be obtained from the association at 5, Tite Street, Chelsea, London, S.W.3.

Medical Students' Conference

The Glasgow Branch of the British Medical Students' Association has arranged a conference for medical students to be held from September 26 to 30, during which lectures will be delivered as follows: In the Pathology Lecture Theatre, Western Infirmary, Glasgow, Tuesday, September 27, 11.15 a.m., Professor C. F. W. Illingworth, "Peptic Ulcers"; Wednesday, September 28, 11.15 a.m., Professor D. F. Cappell, "The Rhesus Factor"; Thursday, September 29, 11.15 a.m., Dr. T. Anderson, "Antibiotics in the Treatment of Infection"; Friday, September 30, 11.15 a.m., Professor S. G. Graham, "Acidosis and Alkalosis," and 2 p.m., Dr. W. A. Taylor, "Hypertension." On September 30, from 9.15 a.m., there will be a demonstration on hypertension in the pathological department of the Western Infirmary. The following lectures will be delivered in the Zoology Lecture Theatre of the University of Glasgow: Monday, September 26, 4.15 p.m., Professor P. I. Dee, F.R.S., "Nuclear Physics in Medicine"; Tuesday, September 27, 4.15 p.m., Dr. P. R. Peacock, "The Effects of Radiations on Experimental Tumour"; Friday, September 30, 4.15 p.m., Professor L. S. P. Davidson, "Partition Chromatography." Members of the medical profession are invited to attend the lectures.

C.M.F. Surgeons' Club Dinner

The annual dinner of the C.M.F. Surgeons' Club will be held at Claridge's Hotel, Brook Street, London, W., on Thursday, September 29. Applications for tickets, with cheques for 25s., should be sent to Mr. Guy Blackburn, M.Chir., Keat's House, Guy's Hospital, London, S.E.1. Evening dress will be worn. Guest tickets are not available.

Contraceptive Technique

A lecture and demonstration of contraceptive technique will be given by Dr. Marie C. Stopes and Dr. Beddow Bayly at the Mothers' Clinic, 108, Whitfield Street, London, W., on Thursday, October 6, at 2.30 p.m. Medical practitioners should apply for tickets well in advance.

Prevention of Accidents

The Royal Society for the Prevention of Accidents will hold a National Safety Congress on October 4–7 at the Central Hall, Westminster. Among the speakers will be Dr. C. A. Boucher, of the Ministry of Health, and Dr. J. A. Gorsky. Particulars may be obtained from the society at Terminal House, 52, Grosvenor Gardens, London, S.W.1.

Welsh National School of Medicine

The opening address of the 1949–50 session of the Welsh National School of Medicine will be delivered on Thursday, October 6, by Dr. William N. Pickles, Medical Officer of Health for Aysgarth.

SOCIETIES AND LECTURES

Tuesday

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At Anatomy Lecture Theatre, Edinburgh University, September 20, 4.30 p.m., *"Bone and Joint Pathology,"* by Professor S. L. Baker.

Wednesday

NORTH-EAST LONDON CLINICAL SOCIETY.—At Clinical Theatre, Prince of Wales's General Hospital, Tottenham, N., September 21, 8.15 p.m., medical films and discussion on public health matters

Thursday

EDINBURGH POSTGRADUATE BOARD FOR MEDICINE.—At Anatomy Lecture Theatre, Edinburgh University, September 22, 4.30 p.m., *"The Bacteriological Principles Governing Chemotherapy,"* by Professor C. H. Browning, F.R.S.

Friday

BIOCHEMICAL SOCIETY.—At Department of Biochemistry, School of Medicine, Leeds, September 23, 11 a.m., 279th meeting.

MIDDLESEX COUNTY MEDICAL SOCIETY.—At Edgware General Hospital, Edgware, Middlesex, September 23, 4 p.m., annual general meeting. *"Focal Hypersensitivity as a Pathological Syndrome,"* by Dr. J. L. Hamilton-Paterson.

ROYAL SANITARY INSTITUTE.—At National Museum of Wales (Reardon Smith Lecture Theatre), Cardiff, September 23, 10 a.m., *"The National Health Service Act (Sections 24 and 28): Advice, Care, and Aftercare,"* discussion to be opened by Mrs. Clarice O'Shea; *"Food Control,"* by Mr. W. M. Shortt, M.Sc., F.R.I.C.

APPOINTMENTS

Drs. F. A. Ibiam, O.B.E., and K. A. Abayomi have been appointed Members of the Executive Council of Nigeria.

HUGHES, A. C. C., M.B., M.R.C.P., Chest Physician, Chester Area, Liverpool Regional Hospital Board.

LANDON, JOHN, M.R.C.S., L.R.C.P., D.P.H., Medical Officer of Health for the Boroughs of Bexley and Erith and Urban District of Crayford and School Medical Officer, Borough of Bexley.

REES, F. T., *M.C.*, M.R.C.S., L.R.C.P., Director-General of Medical Services, Ministry of Pensions, in succession to Sir Francis Prideaux, C.B.E., M.R.C.S., L.R.C.P., who retires on September 30.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

McQuaid.—On September 9, 1949, to Ena (née Green), wife of Dr. T. M McQuaid, 96, Psalter Lane, Sheffield, a son.

MARRIAGES

Black—Gordon.—On August 20, 1949, at St. Paul's Church, Enfield, Alexander L. Black, M.B., F.R.C.S.Ed., to Jeanie F. Gordon, M.B., D.C.H.

Moore—Hewitson.—On September 1, 1949, at St. Albans Abbey, W. E Dodwell Moore, M.B., B.Ch., to Nora Hewitson, M.B., B.S.

Smith—Blatherwick.—On September 10, 1949, at Mere, Wiltshire, D. W. G Smith, M.B., M.R.C.P., D.P.H., to Marjorie Blatherwick.

DEATHS

Densham.—On September 8, 1949, at Parkstone, Dorset, Ashley Densham, M.R.C.S., L.R.C.P., aged 79.

Finn.—On September 11, 1949, at Gatcombe House, Ashwick, near Bath, Patrick Taaffe Finn, L.R.C.P.&S.Ed., L.R.F.P.S.

Forgan.—On September 6, 1949, at Highgate, Robert Berry Forgan, L.R.C.P.&S.Ed., L.R.F.P.S., aged 62.

Gerhard.—On August 29, 1949, at Overbrook, Philadelphia, U.S.A., Arthur Howell Gerhard, M.D., aged 73.

Hay.—On September 8, 1949, Edmund Hay, M.B., C.M.Ed., of 384, Prince Regent's Lane, London, E.

Kearney.—On September 5, 1949, James Kearney, L.R.C.P.&S.I. and L.M.

McCall.—On September 9, 1949, at Rudgwick, Sussex, Annie McCall, M.D.

Martin.—On September 5, 1949, at St. Mary's Hospital, Paddington, London, W., William Whittle Martin, M.B., Ch.B., D.P.H., of the Manor House, Southwick, Sussex.

Moll.—On September 8, 1949, Henry Henderson Moll, M.D., F.R.C.P., aged 53.

O'Connor.—On September 5, 1949, at Old Manor House, Epsom, James Alphonsus O'Connor, M.B., Ch.B., late Indian Army, aged 55.

Roberts.—On September 8, 1949, at Hessle Moor, Heswall, Cheshire, Hugh Leslie Roberts, M.D., aged 89.

Robertson.—On September 6, 1949, at 178, Burnage Lane, Manchester, William Robertson, L.R.C.P.&S.Ed., L.R.F.P.S., aged 78.

Seah.—On August 29, 1949, at Findon, Sussex, Eng Khway Seah, F.R.C.S., aged 50.

Strain.—On September 10, 1949, William Loudon Strain, M.B., C.M., of 4, Hove Court, Raymond Road, Wimbledon Hill, London, S.W.

Walker.—On September 3, 1949, at Aberdeen, James Robert Hall Walker, M.D.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Myasthenia Gravis

Q.—*In view of the antagonism between the action of the thyroid gland and of the thymus, would methyl thiouracil be worthy of trial in myasthenia gravis?*

A.—Thymectomy is of value in myasthenia gravis. An important paper on this subject appears in the opening pages of this issue of the *Journal*. Thyroidectomy is not known to be of any value in myasthenia gravis uncomplicated by thyrotoxicosis, and it is doubtful if it is of value in true myasthenia gravis, which may be present at the same time as thyrotoxicosis but not a sequel to it. On the other hand, thyroidectomy is definitely of value in that form of myasthenia which is a complication of thyrotoxicosis. It is difficult, however, to conjecture that methyl thiouracil would be of any value in idiopathic myasthenia gravis. If it did prove of value it might not be regarded as suitable therapy, because of the need for its persistent application for the duration of the disease. In assessing any form of treatment it must be remembered that myasthenia gravis undergoes spontaneous remissions which may last for many months.

Threadworms in Infants

Q.—*What is the best treatment for threadworm infestation in children under the age of 2? Tablets or capsules are unsuitable for infants because of the inadequate swallowing reflex, and frequent enemata are contraindicated on psychological grounds. Is there anything that can be given in liquid form and still be effective in the large bowel?*

A.—The best treatment for threadworms in an infant under 2 years is gentian violet. The usual plan of dosage is to give 1/6 gr. (11 mg.) daily for each year of age, in divided doses, two or three times a day before meals. The course is usually one of five days with five days' break and then a second five days of the drug. Meanwhile gloves and pyjamas should be worn to prevent night scratching (if napkins have been left off) and a little ammoniated mercury ointment smeared round the anus at night. Unfortunately to give gentian violet there is no satisfactory alternative to capsules, and the administration of these to a young infant is a skilled job. Probably the best solution would be the temporary admission of the child to hospital for each of the five-day periods. If psychological trauma is feared from this, a nurse might visit at home, but the situation demands a nurse trained in work with children, and she is more likely to be successful in hospital. It is worth while remembering that threadworm infestation is often familial, and if a young baby has threadworms then the same may apply to older children or even to the parents, in whom there may be no symptoms. While the infant is in hospital the rest of the family might be investigated and treated if necessary.

Antiseptics for Minor Dressings

Q.—*For constant use in minor dressings acriflavine has the disadvantage that it stains the hands, dressings, towels, etc. Is there any comparably bland antiseptic that does not produce staining (mercury perchloride, for example), and that can be substituted for routine use in the surgery?*

A.—Yes: 5-aminoacridine hydrochloride ("monacrin")—a substance of the same chemical nature as acriflavine, and having a similar action on bacteria and a rather lower tissue toxicity, but non-staining. If the inquirer is referring to prophylactic application to accident wounds there is much to be said for abandoning the use of solutions altogether and thus largely overcoming the difficulty of staining. The alternative method is insufflation of a powder for which the formula in common use is 1 part of proflavine (2:8-diaminoacridine sulphate) in 99 parts of sulphathiazole. Proflavine stains, but for various reasons—notably its constancy of composition, lower tissue toxicity, and lower solubility—is otherwise superior to acriflavine. The advantage of using a relatively much less soluble antiseptic in powder form is that a more persistent effect is obtained than with a solution.

Mercury perchloride is not "bland," it is exceedingly toxic, and should never be applied to any part of the body except, possibly, the intact skin.

Dose of Chloral for a Baby

Q.—*How far can chloral be safely pushed in the symptomatic treatment of restlessness in a newborn child delivered with forceps? Would you consider a four-hourly dose of 1 gr. (65 mg.) harmless if given over a period of two or three days, or could such a dose cause liver damage and/or respiratory embarrassment due to lack of movement brought about by the narcosis? Is it justifiable to give chloral as a routine to "stressed babies"?*

A.—It appears quite safe to give chloral hydrate 1 gr. four-hourly to a newborn child, and this is a recognized form of treatment for infants suspected of cerebral irritation. Usually the dose is gradually reduced as the irritability improves. It is inadvisable to give chloral routinely to "stressed babies." There is usually a cause for the irritability, and this should be sought and corrected. However, there is the irritable infant of a "highly strung" mother that usually responds well to 1 gr. of chloral hydrate before each feed, and this can be continued for several months. Children tolerate chloral very well and rarely show toxic symptoms. It is unlikely to cause respiratory embarrassment in the newborn, but if cyanosis is present oxygen could be given.

Dermatitis Due to Cold Permanent Waving

Q.—*What is the treatment for dermatitis of the scalp caused by cold permanent waving?*

A.—If not due to idiosyncrasy, this is probably a chemical alkaline dermatitis. It may be necessary to cut the hair if there is much exudate and matting. A 0.5% aluminium acetate lotion, or washing the scalp with permanganate of potash 1 in 8,000 followed by the application of liquid paraffin or olive oil, would be suitable. An ointment composed of gentian violet 2½ gr. (0.16 g.), salicylic acid 5 gr. (0.32 g.), coconut oil 120 gr. (8 g.), Halden's emulsifying base 120 gr., with soft paraffin up to 1 oz. (31 g.), is also effective, the head being wrapped in a turban after the ointment has been applied, although the staining may not be appreciated.

The questioner might be interested in an article by Cohen (*Arch. Derm. Syph., Chicago*, July, 1949, p. 14).

Stilboestrol for Prostatic Cancer

Q.—*What is the scheme of dosage of stilboestrol for prostatic cancer, and how long can treatment be continued?*

A.—For cancer of the prostate it is usual to start with a dose of 5 mg. of stilboestrol daily. This is continued for one week, and the dose is then reduced to 0.5 or 1 mg. daily. The amounts given depend on the fall in the acid phosphatase level in the serum, which should be estimated at intervals, and on the response of symptoms, such as the relief of pain. There is therefore no fixed maintenance dose. This treatment can be continued indefinitely, and patients have been treated for several years.

Ozone as an Aerial Disinfectant

Q.—*A machine producing ozone is being installed to improve the stuffy atmosphere of a workroom. Is the prolonged inhalation of even small amounts of ozone harmful?*

A.—The action of ozone on the tissues is similar to that of chlorine: it irritates the mucous membranes, particularly the respiratory and ocular membranes. The *Heating, Ventilating and Air Conditioning Guide*, 1946, states that "the allowable concentrations in the breathing zone are very small, between 0.01 and 0.05 part per million parts of air. These are much

too small to influence bacteria. Higher concentrations are associated with a pungent, unpleasant odour and considerable discomfort to the occupants. One part per million causes respiratory discomfort, headaches, depression, and a lowering of the metabolic rate. . . ." Experimental evidence on the merits of ozone as an aerial disinfectant has led to the conclusion that ozone in concentrations that can be breathed over long periods without irritation cannot be expected to provide any effective protection against airborne bacterial infection. Perhaps the best way to improve a "stuffy atmosphere" in a workroom is by attention to ventilation.

Food Value of Glycerin

Q.—*Has glycerin any food value and does it conduce to putting on weight? I have used jam and marmalade made with glycerin instead of sugar for diabetic patients, as it has little carbohydrate value.*

A.—Glycerin is a trihydroxy-alcohol. It is absorbed readily, and after absorption acts as a source of energy. It is alleged that it lessens glycosuria in diabetics. As a food it spares fats but does not influence protein metabolism.

Fat Deposits

Q.—*A woman has large pads of fat over each hip-joint and the inner aspect of both knees; the swellings in the latter site are discoloured, somewhat inflamed, and a little painful. The upper part of her body, arms, face, neck, and breasts are normal. The patient suffered considerable privation as a Japanese P.O.W. and had beriberi. Treatment by diet, radiant heat, medicines, and glandular products has had little effect. Would this be a case of Dercum's disease, and can you suggest any treatment?*

A.—This description is not typical of Dercum's disease, in which the fat deposits are strikingly tender. It is somewhat more suggestive of symmetrical lipomatosis. However, in both conditions treatment is most unsatisfactory, and the patient in question appears to have tried almost all known therapeutic methods without benefit. As the deposits are so localized, it would be worth her while to consult a plastic surgeon, as possibly excision could be undertaken.

Kaolin and Bismuth

Q.—*During the war, in the treatment of gastric and intestinal conditions, bismuth compounds were largely replaced by substitutes that were more accessible or less costly. Now, although bismuth is readily obtainable, there appears to be a tendency to continue to prescribe the substitutes. Is there any authoritative evidence that salts of bismuth have a superior therapeutic value?*

A.—During the war bismuth compounds were replaced by kaolin. This is a fine powder, like bismuth carbonate, which acts by adsorbing irritant substances. Neither bismuth carbonate nor kaolin has much power to neutralize hydrochloric acid. There is no evidence that bismuth salts have a superior therapeutic value.

Barley Sugar and Cerebral Metabolism

Q.—*I have an elderly male patient suffering from a moderate degree of Parkinsonism. He finds that barley sugar gives him more direct benefit than any of the new drugs on the market. I note that Quastel states that the brain only absorbs nourishment in the form of glucose. Does this mean that table sugar and many forms of confections consisting of sucrose are of no therapeutic value?*

A.—Barley sugar is a vitrified form of sucrose. If the patient derives benefit from its use, therefore, it seems unnecessary to resort to glucose or to foods containing it. While Quastel would agree that glucose, which may be derived with fructose from the hydrolysis of sucrose, is the most plentiful metabolite supplied by the blood stream to the brain, he would hardly support the view that it is the brain's sole source of nourishment. He has himself shown that the brain may metabolize other substances, including glutamic acid.

NOTES AND COMMENTS

Transitory Retrobulbar Neuritis.—Dr. HUGH GARLAND (Leeds) writes: Your feature "Any Questions?" is often useful in supplying the answer to problems the answer to which might otherwise be difficult of access. The quality of the answers is usually high, but I would call your attention to the answer to the question, "What may be the cause, apart from disseminated sclerosis, of a transitory attack of retrobulbar neuritis?" (August 13, p 397). Your anonymous authority prefaces his answer by dividing the causes into three groups, of which the first is "functional disease." One can only assume that by this he refers to hysteria, but, if so, why not say so? He then states that various authors differ in their views about the place of nasal disease and focal sepsis as causes of transitory retrobulbar neuritis without making any critical comment of his own. Surely there is no shred of evidence that retrobulbar neuritis ever results from such localized sepsis. He goes on to state that there is a natural tendency to spontaneous recovery, but the question only relates to transitory attacks. He then proceeds to give a list of causes (presumably which he himself accepts) of the most remarkable diversity. Has anybody ever seen transitory amblyopia caused by alcohol, tobacco, or diabetes? The optic atrophy, enlarging scotomata, and progressive visual failure sometimes complicating pernicious anaemia are by no stretch of imagination transitory, and even with intensive liver treatment improvement is extremely slow. Is there any proof that either syphilis (and, if so, syphilis of what structure?) or plumbism ever causes transitory blindness? Why should post-partum as opposed to any other form of haemorrhage be singled out as a cause of this condition? His next cause is one of classic simplicity, "sepsis." Disturbances of nutrition as a cause of failing vision is presumably a reference to that form of optic atrophy seen not infrequently among prisoners-of-war, but there is nothing transitory about this condition, and so far as I know all the affected persons were left with permanent disorders of vision. In what way, one might ask, can menstrual disorders cause transient amblyopia, unless this be hysterical? And the same would apply to pregnancy.

One by no means uncommon cause of transient monocular blindness which is not mentioned is the aura of an attack of migraine. You might say that here the basis of the visual defect is not "retrobulbar neuritis," but I would suggest that if most of the above causes ever, in fact, operate they certainly do not produce an inflammatory lesion of the optic nerve. The final statement is that "some attempt has been made in this list to indicate the frequency of the causes," but I can find no reference to the frequency either of a single cause or of the condition itself. Surely it is time for the universal recognition of the fact that transient "retrobulbar neuritis" should always be regarded as a manifestation of disseminated sclerosis or one of the rarer demyelinating diseases of the central nervous system.

Acroparaesthesia.—Dr. M. G. GOOD (London, N.W.11) writes: With regard to the question on acroparaesthesia (*Journal*, August 27, p. 495), I should like to say that my personal experiences do not agree with the opinion expressed in textbooks on the nature of this disease, which in recent years seems to have become more frequent. In the last five years or so I have successfully treated more than a dozen cases, mostly in women, rarely in males. In my experience acroparaesthesia is caused by an "idiopathic myalgia" of the elbow. The characteristic "myalgic spots" are regularly to be found in the origin of the flexors and/or extensors of arm and wrist. An appropriate treatment with small quantities of procaine relieves the complaints and cures the disease without delay.

Angioneurotic Oedema.—Dr. S. H. CRAIG (Feeny, Co. Londonderry) writes: With reference to the question and answer under this heading ("Any Questions?" August 20, p. 448), I have suffered from this trouble for 30 years. I had very severe attacks, but I found that sodium citrate 1 dr. (4 g.) in water, increasing the dose by 1 dr. with every attack until I got up to 4 dr. (16 g.), acted like magic and never once failed. The attacks have been getting less frequent and are now only a few times a year.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Aitiology, Westcent, London.* ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are not sent abroad.

ADVERTISEMENTS should be addressed to the Advertisement Manager, B.M.A. House, Tavistock Square, London, W.C.1 (hours 9 a.m. to 5 p.m.) TELEPHONE: EUSTON 2111. TELEGRAMS: *Britmedads, Westcent, London.*

SUPPLEMENT TO THE
BRITISH MEDICAL JOURNAL

LONDON SATURDAY SEPTEMBER 17 1949

THE SECRETARY REPORTS

GENERAL PRACTITIONER CONDITIONS OF SERVICE

Drops of water are said to wear away the stone, and the General Medical Services Committee continues to make representations to the Ministry on a number of points affecting the general practitioner service under the Act. Remuneration is, of course, in the forefront, and the Committee hopes this will be carried a stage further when its representatives meet the Ministry on September 23.

Other matters which are being pressed to a conclusion include the provision of medicines and appliances for private patients; permission to keep stocks of medicines and dressings for emergency use in surgeries; relief from the obligation to issue medical certificates for surgical corsets; permission to obtain *x*-ray and pathological examinations by direct application to the hospital department concerned; provision for charging fees for services outside the range of general practitioner treatment; the payment of a fee to a doctor called in to an emergency following a dental operation, the dentist not being available; the reimbursement of doctors for postage on documents to executive councils; the reintroduction of rules for the conduct of patients which were in operation under the N.H.I. Act; a revision of the wording on the medical card; and permission to reverse telephone charges when a call is made to a hospital on behalf of a patient.

Public Relations at Work

A correspondent recently asked, possibly rhetorically, whether the B.M.A. had a Public Relations Department. He said the public had "no idea of the low remuneration that every family doctor is paid under the National Health Service." The Public Relations Department recently had printed and issued over 600,000 leaflets on precisely this subject, together with 20,000 posters. Supplies have been sent by post direct to every practitioner who asked for them. The Public Relations Department spends a large part of its time answering inquiries from journalists about such matters as remuneration, overwork, delayed admission of patients to hospitals, unreasonable demands on doctors by patients, and various charges of abuse brought against the working of the Health Service. One pressman recently telephoned the Department to say that he had noticed that cases of opium addiction officially notified in this country showed a slight increase and included a large proportion of members of the medical profession. Had the B.M.A. any comment? It was pointed out to him that the increase was very small. "Yes," said the journalist, "but couldn't I say that it was the result of worry caused by the National Health Service?"

Doctors in the Territorial Army

Several letters of complaint have lately been published in the *Supplement* from doctors who are members of the Territorial Army. It appears that the Ministry of Health has asked local executive councils to decide whether such doctors should or should not be embodied with the Territorial Army in another emergency. If the Ministry is advised by the local executive council that a particular doctor is indispensable in civilian practice in his area then he will not be embodied with the rest of the Territorial Army. The doctors concerned are apparently not to be consulted.

Two issues arise here. First, the existing and highly successful machinery for the mobilization of doctors for National Service is the machinery devised by the medical profession itself—namely, the Central Medical War Committee, Scottish Central Medical War Committee, and the Local Medical War Committees. This machinery is still in existence—it has continued to exist since the end of the war at the express request of the Minister of Health himself. In communicating with the executive councils about the embodiment or deferment of particular Territorial Army doctors the Ministry of Health has deliberately by-passed this machinery. Secondly, the decision whether or not a particular Territorial Army doctor is to be embodied with the remainder of the Territorial Army is apparently to be made behind the doctor's back. Many of these practitioners have voluntarily given long hours of their spare time on weekly drill nights and a week or more of their annual holiday at annual camps. If another emergency arises some of them will find that, by arrangements made without their knowledge or consent, they are not called up with their comrades and all their voluntary spare-time work is wasted. The Association is protesting most vigorously against this tactless and inconsiderate procedure.

World Medical Association

The British Medical Association is to be the host of the General Assembly of the World Medical Association when it meets in London next month. It promises to be an interesting meeting. Twenty-two countries will be represented, and eight international medical organizations will send observers. The delegates of the British Medical Association will be Dr. Guy Dain and Dr. J. A. Pridham, with Dr. E. A. Gregg and Dr. S. Wand as alternates. Dr. Charles Hill is to be elected President of the World Medical Association for the coming year. The outgoing President is Professor Eugene Marquis, of France.

Among the subjects to be discussed by the Assembly will be a draft international code of medical ethics. The preparation of this code follows upon the W.M.A.'s consideration of the part played by certain members of the profession in the perpetration of war crimes and the adoption last year of the "Declaration of Geneva." The new "code" is to be an amplification for practical purposes of the principles laid down in the Declaration. During the past year the council of the W.M.A. has been collecting information about the schemes for "social security" in existence in the different countries, with special reference to the medical services and the extent to which they conform to the principles of public medical service adopted at Geneva last year. The council has also been collecting information about postgraduate education for both specialists and general practitioners, and this will be the subject of a report to the Assembly.

The *Bulletin* of the W.M.A., under the editorship of Dr. Morris Fishbein, of the U.S.A., with the assistance of collaborating editors from other countries, will reach its third number in October. It appears to be serving a useful purpose in medical literature, and the Assembly will consider what improvements can be introduced.

PHYSIOTHERAPY SERVICES

REGIONAL ARRANGEMENTS

The Minister of Health, according to a recent memorandum issued by the Ministry, is advised that the maximum benefit of modern physiotherapy is to be obtained under specialist supervision in fully staffed and equipped hospital departments. Furthermore, the shortage of adequately trained personnel, which will continue for an indefinite period, makes it imperative to concentrate them in hospital departments where their services can be employed to most advantage. Accordingly, physiotherapy in the National Health Service should be provided only under specialist prescription as part of the hospital and specialist service, and responsibility should be accepted by regional boards only for treatment prescribed by hospital specialists and carried out under their supervision.

General practitioners who consider that their patients require physiotherapy will normally refer them to a hospital, and if the specialist prescribes physiotherapy it should be provided in accordance with the arrangements outlined in this memorandum. General practitioners of course can use their own equipment to administer physiotherapy treatment to patients, but boards and management committees are not concerned with such arrangements.

Regional hospital boards are therefore responsible for organizing a satisfactory physiotherapy service in their regions. Regional hospital boards were advised in R.H.B.(48)53 (now superseded by this new memorandum R.H.B.(49)114) that in rural and other areas where it appeared necessary to supplement the hospital facilities they could contract with existing public organizations which provide physiotherapy services (e.g., British Red Cross Society, District Nursing Associations, etc.), or, very exceptionally, with private physiotherapists, to treat patients for whom physiotherapy had been prescribed through the hospital service. The system of contracting with private physiotherapists has proved in some areas to be expensive, and is necessarily an uneconomic method of providing treatment under the National Health Service. Accordingly, where it proves necessary to supplement hospital facilities—either because of distance or because of lack of accommodation in the hospital, or for other reasons—regional hospital boards should organize full-time or part-time clinics in suitable towns or villages which should be conducted by physiotherapists based on the nearest hospital with an adequate physiotherapy department. This expanded and mobile physiotherapy service should be organized on the same lines as the orthopaedic service in some areas, making use of existing halls, health centres, or other suitable buildings. Physiotherapists now in private practice should be employed full time or on a part-time basis in the hospital service.

As these clinics come into operation in areas where there is a need for them, contractual arrangements will become unnecessary, and they should be discontinued as soon as possible. In the Minister's view it will be found more effective as well as more economical to employ additional physiotherapists, whether whole-time or part-time, as members of the staff of the hospital service and carrying out their work within the service, than to seek to continue contractual arrangements whether with individual physiotherapists or with public bodies employing them.

Evening Sessions and Domiciliary Treatment

Loss of time by patients at work with consequent loss to the national economy should be prevented by arranging evening sessions. It is estimated that between 10 and 15% of patients attending physiotherapy departments require evening treatment, and arrangements for it should be made wherever the need exists.

Only in exceptional cases, when it would be harmful to convey the patient to the nearest hospital or clinic, should treatment be provided in the patient's home. Responsibility for domiciliary treatment should be accepted by boards only when prescribed by a hospital specialist either at hospital or through a domiciliary consultation. In such cases treatment should normally be given by physiotherapists based on the nearest hospital or clinic as part of their full-time or part-time work.

Representations have been made to the Minister that there are some signs of a decline in the amount of work being done by blind physiotherapists. It is important that the fullest possible use of their services should be made. The Minister recognizes the peculiar convenience to the blind of work near their homes, and suggests that hospital management committees and boards of governors should give careful consideration to the possibility of appointing blind physiotherapists to any suitable vacancies on the staff of hospital departments and associated clinics, particularly any situated near the blind physiotherapist's home.

DOMICILIARY MIDWIFERY

DOCTORS AND MIDWIVES

In order to avoid the difficulties arising between doctor and midwife regarding the capacity in which the midwife is to act in a particular case, the Local Medical Committee and Health Department at West Bromwich have devised a simple scheme of notification which seems to have worked well in practice. A card which fits part 1 of Form E.S. 24 has been designed to read as follows:

NATIONAL HEALTH SERVICE
MATERNITY MEDICAL SERVICE

To the Domiciliary Midwife,

Re Mrs. .....

.....

I have agreed to take this case.

Date..... .....
(Signature of Doctor.)

Your services will be required as $\frac{MN}{M}$

The card is placed under Part 1 of Form E.S. 24 with a carbon so that the particulars are automatically entered. Either midwife (M) or maternity nurse (MN) is deleted according to whether the doctor proposes to be present at the confinement in any event or only if specially required. The card is given to the patient who is instructed to hand it to the nurse. The nurse is thus made aware of her exact position in the case and of the name of the doctor who has accepted the case.

Further, when acting as a midwife, she knows which doctor to notify when the confinement has taken place. In West Bromwich the M.O.H. has undertaken to notify practitioners that the birth has taken place, the name of the doctor concerned being given to the M.O.H. by the midwife on the formal notification form.

EMERGENCY TREATMENT: ROAD ACCIDENTS

Model forms for use in submitting claims for payment of the fees allowed under the Road Traffic Act, 1934, are still obtainable from the Secretary of the British Medical Association. Under this Act a fee of 12s. 6d. is payable where emergency treatment or examination is immediately required as a result of bodily injury (including fatal injury) to any person caused by, or arising out of, the use of a motor vehicle on a road and the treatment or examination so required is effected by a registered medical practitioner. An oral request for payment of this fee may be made to the person responsible, or, if no oral request is made, a claim must be submitted in writing within seven days from the date of the emergency treatment. The person who was using the vehicle at the time the event occurred out of which the bodily injury arose is the person responsible for the payment of the practitioner's fee, and the fee is payable whether or not the patient is on the doctor's list. Where more than one car is involved it is not for the doctor to decide which is to blame, and the claim in doubtful cases may be submitted to the driver of either vehicle.

PAY OF MEDICAL OFFICERS IN THE ARMED FORCES

An interim reply has been received from the Ministry of Defence to the Association's proposals for improvement of pay of medical officers in the armed Forces. In the reply it is pointed out that changes in the emoluments of Service medical officers cannot be considered in isolation from the emoluments generally of the Service of which these medical officers are members. As a result any proposal for the revision of the pay of Service medical officers raises issues of much complexity. It is hoped, however, that decisions will be reached before long.

The reply then goes on to make the interesting statement that the remuneration of personnel in the armed Forces is decided by the Government and that "negotiations" with associations representing any section of the armed Forces have never been undertaken. It is stated that such "negotiations" would be incompatible with Service discipline. This doctrine may or may not be true, but the Ministry of Defence has to recruit doctors from the same market as everybody else, and the plain fact is that voluntary recruitment of medical officers to the armed Forces has dwindled practically to nothing. It has not escaped attention that the Army is even attempting to hire civilian specialists to serve for limited periods on special terms. One does not know what will be the effect of these appointments on the regular specialist medical officers when the latter find that the short-term civilians are receiving much higher rates of pay.

HEARD AT HEADQUARTERS

Transatlantic Methods

Medical men who have been visiting the United States this summer have come back full of admiration for the technical wonders of American medicine, especially for the clever, dexterous surgery and the efficient hospital organization. Some of the rewards of medical men in the States also make the mouth water. One British surgeon who lately visited New York came back with the opinion that in that city most of the surgeons are earning incomes of about 100,000 dollars a year. In California one proctologist was mentioned whose income is 170,000 dollars. The visitors speak also rather wonderingly of the cost of private hospital beds. The cost is so high that even well-to-do patients can afford to remain only the minimum time. Accommodation which would rank here at about 14 guineas a week runs to 40 guineas in the States. Yet the most enthusiastic admirers of the American way of life seem to retain an unconfessed partiality for the British way of medicine.

The Phone-sitter

We have always had the feeling that more might be done with the telephone. Some intelligent extension, for example, might enable the instrument, when a call is unanswered, to leave a message. That does not seem much to ask in view of other triumphs in sound transmission and recording. Failing a really satisfactory system of that kind, some doctors have gone to work on their own and established a phone-sitter. In South Derbyshire, in a large group of villages centred on Swadlincote, they have organized an emergency telephone system. If the telephone call is made after surgery hours and the doctor is not at home the caller may, through an emergency call, be put in touch with another doctor who is available. The operator at the private emergency phone, whose number is being published throughout the district, has a list of names and numbers of all South Derbyshire doctors, and knows at what times they are available in the evening. If a doctor is urgently needed and the caller gets no answer from his own doctor, he rings Swadlincote 7441 and immediately is given the name of a doctor known to be available. The second doctor only puts in the one attendance, of course, the patient belonging to the first doctor. The interest of telephone exchange operators, industrial concerns, police, nurses, local hospitals, and public health services is being sought, and the plan bids fair to be a success and to bring much-needed relief to harassed practitioners, who deserve their evening off like other people.

A Busy August

What has been the position of doctors this summer from the point of view of work? The verdict of some in busy town practices is that it has been the busiest August in their experience. In holiday centres, too, visitors have shown themselves N.H.S.-conscious to a surprising degree. One practitioner says that it is not so much the number of callers that he minds as that, once the caller is admitted, it is so difficult to get rid of him. It is not one complaint he mentions but a group of complaints, and he wants attention for them all. Sometimes, too, the patients are not as considerate and polite as they might be expected to be. One doctor with a busy practice in the Midlands says that his wife, attending the telephone, has never been so much insulted before. The voice at the other end is more abrupt and demanding than it used to be. "I have told the doctor to come, and that is all there is to it," or some such phrase, is too often the caller's last word.

Questions Answered

Part-time Specialist

Q.—*I desire to know what is the correct procedure for me to undertake if necessary to be recognized as a part-time consultant, having already been so classified as a specialist-surgeon by the B.M.A. and yet again accepted as such by the R.A.M.C.*

A.—If a specialist already has an established appointment on the staff of a hospital, he will be classified by the review committee. If he holds no such post, he will acquire specialist status only after successful application for an appropriate appointment.

Compensation

Q.—*Can you advise me when compensation will be paid if one leaves the Service, and has the rate of same been arrived at*

A.—Compensation is payable on retirement from practice as a medical practitioner providing general medical services under Part 4 of the Act or Part 4 of the National Health Service (Scotland) Act, 1947 (Compensation Regulations, 13 (3)). It will not be possible to fix the exact rate, expressed in years' purchase, payable to individual practitioners until the aggregate of all claims is known. This cannot be ascertained until at least two months after the passing of the Amending Act. Any doctor who claims to suffer hardship through delay is entitled to apply for a payment on account.

Deductions from Assistant's Salary

Q.—*I shall be grateful if you will give me the details of the deductions required to calculate the net amount to be paid to an assistant whose gross salary as outdoor assistant is £1,000 per annum. I refer, of course, to deductions for stamps, superannuation, etc. He is paid monthly.*

A.—Deduction should be made as follows: (1) *Superannuation.* The principal is responsible for the recovery from the assistant of 6% of the assistant's salary (excluding car allowance), *i.e.*, £60 per annum. (2) *National Insurance.* The assistant is required to pay 4s. 11d. per week (3s. 10d. in the case of a woman) as the employee's contribution to National Insurance. The monthly deduction in respect of superannuation and national insurance in the case of an assistant earning £1,000 would be approximately £6 1s. 4d. (3) *P.A.Y.E.* The assistant should produce income-tax form P.45 or obtain a code number from the local Inspector of Taxes. The principal should obtain a tax deduction card, P.11, from the local office, which will also furnish him with the necessary tables showing the amount of tax to be deducted monthly.

Correspondence

Grading of Hospital Staff

SIR,—Our profession was once characterized by dignity, chivalry, and, above all, humanity. Have we lost our soul in the trials and frustrations of the past year? The most colossal injustices are being perpetrated. Every doctor to whom one may speak is horrified. Yet the only reaction appears to be an occasional letter in the Press. The Ministry's guiding principle in extending this obnoxious grade of S.H.M.O. is "divide and rule."

A meeting some months ago of all consultants in this sub-region unanimously demanded that this grade be used only according to the Ministry's original promise. Whilst our colleagues are being deprived of their livelihood we, who are more fortunate, are advised by our leaders to enter the Service, for have they not secured the remarkable concession that clinical teachers will be adequately paid?—a nice commentary on the representative nature of the negotiating body! We were then told that many of the anomalous gradings were due to lack of precise information and would, of course, be amended on appeal. Now that the appeal results are coming through we find that the grading committee is unrepentant in its perversity.

In this city we have four general surgeons solely in consulting practice. Two of them, both about 40 years of age, both over twelve years qualified, both with fellowships and hospital appointments, have been graded S.H.M.O. These men have done nothing but surgery for the past twelve years and are recognized by all the practitioners in the town as consulting surgeons. They run their hospital out-patients along with us and do the customary major operative lists. There is no possible question that these men fall within the category envisaged by the Spens Committee for consultant status and salary. An anaesthetist, only six years qualified, is graded as a consultant (good luck to him).

An even better example of the chaotic state of this region. An officer at the mental hospital left six months ago to take up another post where he has now been graded as a consultant. Our grading committee, unaware of his move, has published the result of its deliberations on him—a J.H.M.O.

The medical advisory committee to the regional hospital board, of which committee I am a member, has protested vehemently against these proceedings. We are completely powerless, and it seems that the board itself is equally so.

Let us review the constitution of these grading committees. Who proposed the members we do not know. We do know that they had to be approved by the Ministry of Health. We know that they were summoned to a secret meeting at the Ministry. What instructions did they receive? Were they told that in order to avoid the expense of honestly implementing the Spens Report a certain proportion of consultants must be downgraded? All the committees, review boards, etc., are unpaid except this grading committee. It is significant that them alone the Ministry pays for their work. Are they paid in pieces of silver?

Those responsible for this travesty of justice are our own colleagues, as the Minister is never tired of reminding us. Will the profession still remain silent? We have men of good will—Lord Horder, Dr. Walshe. There is much we can do. We can resign from all committees and refuse to take any part in running the Service until these injustices are remedied. We must act now, and unanimously.—I am, etc.,

Southsea. J. C. PRESTWICH.

Grading Ophthalmic Specialists

SIR,—Mr. Frederick Ridley (*Supplement*, August 20, p. 96) must be congratulated for so bravely coming to the aid of his less favourably placed ophthalmic colleagues. As he says, there is a very large body of clinical assistants holding postgraduate diplomas, many of whom have held house and registrar appointments, all with several years of whole-time ophthalmic experience. Prior to N.H.S. these men and women were accepted as specialists in their own locality by general practitioners, and many occupiers of provincial honorary staff appointments would come in this category had they elected to remain in the academic centres.

As Mr. Ridley observes, these "specialists" do not fit fairly into S.H.M.O. grading, and it is manifestly unjust that a provincial "honorary" should be refused consultant status, as, if rumour be true, is already occurring. In ophthalmology this group of clinical assistants (Mr. Ridley's "second and much larger group") outnumbers the honorary staff consultants and on an S.H.M.O. grading will be asked to accept a salary far less than that earned prior to N.H.S. I feel Mr. Ridley's terminal suggestion should be considered by the authorities, or it will be difficult to cope with ophthalmic out-patients if the clinical assistants are antagonized.—I am, etc.,

London, W.1. H. F. MELHUISH.

Grading of Anaesthetists

SIR,—Your correspondent "K" (*Supplement*, August 13, p. 83) strikes an important note when instancing that all the visiting staff in teaching hospitals were "unanimously" graded as consultants, irrespective of the fact that some were indulging in private general practice and N.H.S. general practice and some had no higher qualification. Particularly was this so with occasional "anaesthetists." Even in the instance of the smaller hospitals many of these "consultants" slipped through the back door. Of all the disproportionate anomalies, surely the most glaring is the payment of the same fee to an anaesthetist as to a surgeon.—I am, etc.,

"K.2."

Qualifications of Specialists

SIR,—Your correspondent, "Sic Vos Non Vobis" (*Supplement*, August 20, p. 96) strikes the right note in his plea that specialists should have three higher qualifications. I feel, however, that he has been too lenient in his requirements, and that every would-be specialist should have at least five higher qualifications. After all, every physician or surgeon should be able to interpret his own *x*-ray pictures, and so should possess a diploma in radiology. Similarly, in order to prevent unnecessary operations or investigations being performed upon neurotics, a diploma in psychological medicine should be held. It has, moreover, long been held that the modern surgeon is becoming a mere technician, and so a good case could be made for insisting that every surgeon be a Member, and preferably a Fellow, of the Royal College of Physicians.

After these academic qualifications have been obtained, a medical practitioner should spend at least 30 years in the practice of his chosen specialty, and only then should be eligible for the post of consultant. It is only in this way that we can uphold the high prestige of our noble profession.—I am, etc.,

PER ARDUA AD ASTRA.

N.H.S. Pros and Cons

SIR,—With all the criticisms levelled against the National Health Service you may be interested in my observations of practice under the scheme as compared with a large general practice in Johannesburg, South Africa. I have been on exchange for five months now, and can record my own opinions as I find conditions in this practice. I am not in a position to compare this practice with other similar-sized practices under the National Health Service, but I have had an opportunity to discuss and compare notes with other general practitioners in this area, and their experiences do not differ substantially from mine.

ADVANTAGES

The main advantages of practice here are:

(1) *Security of Income.*—A practitioner with a large panel is assured of a reasonable income and can budget accordingly.

(2) *Expenses are Low.*—One does not have to employ a receptionist; there are no bills for stationery, account forms, stamps, etc. (In my own practice nearly 1,000 accounts are sent out at the end of each month.)

(3) *Visits.*—Are localized to within a small radius of the surgery, thus reducing wear and tear on the car and saving a good deal of time. (In Johannesburg my partner and I each cover some 60 miles a day visiting patients.)

(4) *Regular Hours.*—With the regular surgery hours one has a fair amount of leisure between morning and evening surgeries. In my experience here most patients are co-operative. Most of the calls are in before the end of the morning surgery, and can be completed before lunch. With the exception of confinements I have had very little night work, and the few night calls have been genuine. Few of our patients take undue advantage of the "free service."

(5) *One is Not Harassed.*—I find worry far more exhausting than work. In private practice one is often tyrannized by patients demanding preferential treatment "quickly." Here, if I am harassed it is by the work, not by the patients.

(6) *Freedom of Prescription.*—It is a great feeling of satisfaction to be able to prescribe what one feels necessary without having to consider the expense to the patient. Recently a consultant prescribed a course of sex hormones for one of our patients. These hormones are most expensive, and the course of injections prescribed would have cost the patient privately about £30. People of slender means can now afford the luxury of diagnosis and treatment.

(7) *Freedom to Call on Ancillary Services.*—Another great "worry saver" is the ability to call on the experts in a difficult case without having to consider the expense to the patient.

The nursing services are a great help, and I must make special mention of the group bed service. I have found the ladies in charge most friendly and helpful in finding beds for hospital cases. The time they save one in arranging for a patient's admission and transport is invaluable.

DISADVANTAGES

(1) *Volume of Work.*—The main disadvantage of the Service is occasioned by the volume of additional work entailed in catering for a vast number of people. A large number of people attend every surgery, and one has to see them all in a limited time period. One naturally cannot give every patient a routine examination, but comparatively few need it. One learns quickly to "spot" the really ill patients, and, speaking for myself, I have not hesitated to spend as much time as necessary on those really needing it. In the days when one dispensed for private patients a lot of time was spent in the dispensary.

It is impossible to take a lengthy history and keep a record of every case.

(2) *The Hospital Services are Overtaxed.*—Patients have to wait a long time for hospital appointments, and the supply of beds is totally inadequate to the demand. The result of this is that the practitioner has to wait a long time before he gets a report on a referred case.

(3) *Clerical Work.*—A great deal of time is taken up in writing certificates, reports on patients, filing of new cards, removing and dispatching of deletions, etc. This is inevitable; the alternative would be chaos. So far as the authorities are concerned, they have done their best to minimize the work for the doctors. Most certificates merely need the signature, date, and diagnosis. A clerk, even part-time, can take a lot of the routine clerical work off one's hands.

On the whole the advantages more than outweigh the disadvantages, and I feel sure the Service will improve considerably as time goes on. It is certainly a boon to the man of limited means. With the introduction of a higher capitation fee and a reduction in the size of panels I feel the practitioner would devote more time to the individual patient.—I am, etc.,

J. S. ZIDEL.

Thornton Heath, Surrey.

Telephones

SIR,—I notice with pleasure that the medical profession is at last waking up to this telephone ramp or racket. I refer to Dr E. J. Jenkins's letter (August 27, p. 417) and Dr. Thomas Leven in "Points from Letters" (p. 420).

In the days when I was so stupid as to think the duty of the executive council was to help the practitioners on its lists I sent the clerk the following letter, dated March 4, 1949:

"DEAR SIR,—I should be obliged if I could have the benefit of the advice and guidance of the executive council.

"I find that my telephone rental exceeds my income from the National Health Service. Until I joined this Service the G.P.O. allowed me to keep on the "domestic" rate, but now insist that I should pay "trade" rates and have it dated back to July, 1948. (Naturally I am protesting in the hope of putting off the evil day.) Do the council consider that a telephone is essential for doctors on their list? Would the council grant me permission to do away with it for professional purposes? Even if this be given, the G.P.O. will not allow a domestic telephone if there is a professional plate outside the house, and so, as my plate does not seem to produce any benefit to me, perhaps the council will allow me to remove that as well in order to satisfy G.P.O. regulations. Members of other professions satisfy these regulations and rent a "domestic" telephone by having their advertisement on an enormous board outside their churches, chapels, synagogues, or what not. When we have our health centres I am willing to have my advertisement plate there complete with my domestic telephone number. Although I am fed up with some of the regulations to say that a N.H.S. doctor may have a telephone and a plate, it is future that the council should be good enough to gracefully give permission for their removal. At present they could grant the basic salary in order to keep up these appearances, but that is another matter."

"As my telephone account is now overdue an early reply would oblige."

The reply, dated March 29, stated the matter had been considered by an appropriate committee but they were unable to agree to your suggestions." I followed this up with a request as to what were the barest essentials required by the executive council for a practitioner to provide out of his own pocket. After two "hasteners" I received the helpful reply on May 18 that the clerk had nothing to add to his letter of March 29.

I think it disgraceful that the G.P.O. should differentiate against us doctors as compared with ministers of religion, and I think it most uncharitable that our executive council should not help us to overcome this ramp. I should like to know if any of your correspondents can suggest what action the executive council could take if one did do away with the telephone. Dr. Jenkins and I may be legally correct to do away with our telephones, but we have to reckon with our employer, the executive council, which, having the ear of the Minister to the exclusion of its employees, can do as it pleases with its panel slaves. I add my support to Dr Thomas Leven that the B.M.A. should demand that this expense of telephones be met by the National Health Service, but I am pessimistic as to the result.—I am, etc.,

South Harrow, Middlesex. I. PITT PALMER.

Consultants and Specialists

SIR,—With regard to distinction awards, and a few other problems that are a source of worry at present, may I make a few suggestions that might prove helpful? Distinction awards could best be voted for, by a secret ballot, by the assistants of each consultant. They, above all others, are in a position to judge how much time and attention is given to patients. Each consultant could be judged by the proportion of letters to him that he received. But let the ballot be secret, for human nature is frail.

Drugs for private patients. Though it seems unfair for patients who for some good reason of urgency, such as being very short of time, chose to be private patients to have to pay for their drugs on top of their doctor's fees, there is no denying that those who think in terms of private patients are in the habit of luxury prescribing. Why should all secret drugs in the *British Pharmacopoeia* be allowed? If anything under a special trade name was ordered it would have to be paid for unless a satisfactory explanation could be given.

Why not abolish the Consultants and Specialists Committee or make it function? There are at present only "consultants" and "also-rans"—i.e., various odds, ends, and "part-time medical officers." This is by one of the latter.—I am, etc.,

London, W. ANTHONY HOWARD.

Good and Evil

SIR,—Dr. L. S. Woolf (*Supplement*, August 27, p. 195) surely mistaken in thinking that in the future doctors should be able to get places in heaven with the good they do if they get them under the N.H.S. Such a view is in part completely at variance with Anglican doctrine and in part a view is accepted we may soon find ourselves in the position of "in N.H.S. benefits" and that only. Some people will be able to replace the fear of hell with the fear of the Minister of Health. The righteous will of course do all possible to earn their full stipend and pay for what they need in the form of penance.

That the N.H.S. could run as Dr. Woolf says and pay bonus of grace to others that are worthy of such payment is a matter of opinion and not of fact. In the absence of evidence in the form of actual service and practice I

whole idea of the N.H.S. itself. It was said long ago by one who laid down absolute and final standards of good and evil, "Ye shall know them by their fruits," and "Can a corrupt tree bring forth good fruit?"

There will certainly be "no health in us" as a profession or a nation whilst we continue to argue about details of the N.H.S. in operation, and fail to see that it is only a particular instance of the age-old problem of good and evil.—I am, etc.,

Bournemouth. DAVID HARDIE.

This Medicine

SIR,—Shortly after a prospective Tory M.P. had phoned to ask me how he could claim the refund of a chemist's bill for 7s. 3d., incurred privately, a farmer drove in. He had come to ask for a certificate in support of his application for supplementary petrol, because he had had to drive himself to hospital for out-patient treatment. The next phone call was from a glider factory, requesting some certificates about an employee's illness, so that their auditors would not query items of "sick pay."—I am, etc.,

RICHARD N. THEAKSTON.

Payment of Locums

SIR,—I know that I shall be raising a hornets' nest about my ears in bringing this problem up at all, but I feel it will be worth it. The common belief held by the public that doctors, as a class, were not particularly interested in money and not moved by mercenary impulses is now, very rightly, fast disappearing. How rightly is shown by the mean and ungenerous way in which most doctors, when acting as principals, behave to their assistants or locums.

Take the case of the locum. The average fee offered is 14 guineas a week, plus 2 guineas a week car allowance, plus accommodation. Some more generous-minded principals offer 16 guineas a week. We all know perfectly well that the spending power of the £ now, as compared with 1914, is, according to official figures, only 7s., and I feel strongly that 3 guineas a day (especially when the day usually means being on call for 24 hours) is the minimum that ought to be enforced on all doctors when employing a professional colleague. And 2 guineas a week car allowance is simply ridiculous. We all know perfectly well that when our own cars break down the least we have to pay for the hire of a car is 10 guineas a week. Here again a minimum of 4 guineas a week car allowance would be by no means unreasonable and should be agreed to generally by the profession.

The remedy is not the obvious one, and is not necessarily in the hands of the locum. Too often the locum or would-be locum is too hard up to make a stand about this, and has to submit to being exploited by his professional colleagues.—I am, etc.,

"AN OCCASIONAL LOCUM."

Permanent Assistant

SIR,—I have been reading the correspondence regarding principal and assistant with interest until I noticed the letter by "P. Q. R." (*Supplement*, August 27, p. 118). I qualified M.B., Ch.B., 1941, and having spent the usual time as resident in hospital I joined the R.A.M.C. Coming back to this country, I entered general practice as an assistant after a three months' refresher course in hospital.

In my three years as an assistant I have spent a year with three different principals, for the simple reason that at the end of a year's tenure when I asked what my prospects were I was politely told that I was a permanent assistant, and that they had no intention of taking a partner ever. In each case I moved, realizing the logic of their argument, which enables them to have more than half their work done whilst they can enjoy the extra capitation fees 6,500 patients bring. It surely is time that the plight of assistants was investigated. To the public we are assistants and will always be treated as such, yet if there are any night calls the assistant is there to do them. Also it is galling to read advertisements for trainee assistants with a salary of up to £200 a year more than your own.

And finally the prospect of being an assistant for years to come, moving gipsy-like from place to place, hoping for one's Shangri-La, is not a pleasant one, but is one that must face many doctors of my own age, who are not allowed to put up their own plate, who are exploited by their well-to-do principals as a form of slave labour, and whose chance of acquiring a practice under this National Health Scheme is as rosy as that of the poor befuddled fool who fills in his football pool each week. All I can say to "P. Q. R." is that he is a lucky member of the community to be in the position he is in, for I would willingly get into debt to obtain a practice of my own.—I am, etc.,

X.Y.Z.

Practice Vacancies

SIR,—Dr. W. Stanley Sykes (*Supplement*, August 27, p. 118) by juggling with some figures comes to the conclusion that at the age of 55 and after 28 years of practice he still has 72 years before he retires. Notwithstanding his protestations at disconcertment, he must like the new scheme, or he could retire within three months and collect his compensation without the expense of advertising or a commission to an agent. Or is it that in the 27 years of practice under the much-vaunted "free medicine" he has not been able to provide for his retirement?

Let us now look at his facts and figures from a more realistic viewpoint. Is it not possible that the great number of practices advertised for sale each week pointed to dissatisfaction of the doctors concerned with their lot? As I do not suspect Dr. Sykes of being a disciple of Bernard Shaw, nor are the majority of general practitioners potential Methuselahs, his inferences from the number of 20,000 G.P.s in practice are erroneous. Let us take that on the average they will work a further 20 years each. This will cover the older men with anything up to 10 years' work ahead and the youngsters with 30 years of activity to look forward to. This means that even without any extension of the scheme 20,000 new G.P.s will be absorbed within 20 years. One thousand a year, not counting the needs of hospitals, public health authorities, etc. Surely a very attractive profession to consider with its generous retirement scheme.

I spent my holiday this year in a famous French seaside resort, well known for the longevity of its population, which is 10,000. During the first week there I saw six funerals, and on inquiry I learned that these were all of local inhabitants. Had I used Dr. Sykes's system of statistics I would have arrived at a death rate of 31.2 per thousand. For comparison I give you the figure for Romford for 1948—8.2 per thousand.—I am, etc.,

Romford, Essex. LEON M. SHIRLAW.

Association Notices

Diary of Central Meetings

SEPTEMBER

28	Wed.	Private Practices Committee, 2 p.m.
29	Thurs.	Non-professorial Group Committee, 2 p.m.
29	Thurs.	Ethical Rules Subcommittee, 2 p.m.
29	Thurs.	International Relations Committee, 2.30 p.m.
30	Fri.	Ophthalmic Group Committee, 2 p.m.

Branch and Division Meetings to be Held

KENSINGTON AND HAMMERSMITH DIVISION.—At Postgraduate Medical School, Ducane Road, London, W., Friday, September 23, 8.30 p.m., clinical meeting.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Redditch (restricted to new appointments), Tyldesley.

THE USE OF EXPERIENCE*

BY

Sir HENRAGE OGILVIE, K.B.E., M.Ch., F.R.C.S.

Surgeon to Guy's Hospital

We are constantly receiving impressions by all our senses—by touch, sight, sound, taste, and smell—and all these impressions are experience. The baby starts to convert experience into knowledge: before it can talk it is already grouping impressions by their likeness or their difference, and forming vague conceptions like "mother," "food and hunger," "dangerous and friendly." The growing child, the adolescent, the grown man and woman, continue the same process. Impressions crowd in upon them, giving them the raw material—experience—which is converted into the finished article—knowledge—in the factory of the mind.

Experience comes to all. It comes equally to rich and poor, old and young, just and unjust. Yet some learn from it no more than a reflex existence, the knowledge to eat and sleep and breed, to read the thoughts of others on the printed page or live the emotions of others on the lighted screen, to exchange a small assortment of hackneyed phrases with other robots. Some build up knowledge and become wise: they develop a personal outlook that enriches others and adds to the store of their time. The reason for these differences lies not in the quality of the seed but in that of the soil on which it falls. Impressions are fleeting things. They cannot live unless they are welcomed, studied, compared, classified, and grouped. Experience can be made useful only by certain qualities of the mind, some given by inheritance, some by parental example, some by the influence of teachers or writers.

Failure to Learn from Experience

People fail to learn from experience for three reasons. First, because they have not learned the habit of thought. They bolt their impressions without savouring them, as a dog bolts his food. They do not take their raw material into the factory, but let it pass straight from the delivery gate to the refuse dump. They never classify—that is, they never say to themselves, "Something like this happened before in the same circumstances." Thus they never take the next step, from experience to experiment, to deciding, by repeating the circumstances, whether the likeness observed between two experiences was an accident or a consequence.

Secondly, because they have classified too much, or rather because they have allowed their habits of thought to become automatic. They have organized their factory for mass production, so that it cannot deal with the unusual order. They unconsciously shut out all new experience by classifying everything under headings already fixed. Thus astronomers dismissed for years the observed experience of the variations in the perihelion of Mercury by classifying them under the heading of instrumental error, and correcting for them by averaging observations. Thus scientists in the last war boosted a valueless antiserum for gas gangrene because it had been proved in the laboratory to protect mice from the effects of the intraperitoneal injection of cultures of *Clostridium welchii*, and supported their advocacy by a series of meaningless observations in the field, while ignoring the significant experience that men transfused early and adequately with whole blood seldom got gas gangrene.

Thirdly, because, having made the whole of one branch of knowledge their province, they fail to attain that last achievement of education, the knowledge of where their experience is inadequate, of where their knowledge ceases and their ignorance begins. Having acquired supreme mastery of one department of learning they are apt to assume that the whole is theirs, to forget that the highest wisdom is the realization that no man can know everything, that he is indeed wisest who knows his ignorance and where to turn for help when he needs it. One of the greatest physicists since Newton died needlessly and before his time because he treated his own strangulated hernia with household remedies and turned only many hours too late to those who had made such ailments their life's study and who could have saved him.

The beginner fails to use experience because to him it is so multitudinous that he cannot handle it until he has acquired some of the technique of the warehouseman or filing clerk. The learned man is often blind to new experience because the mass of knowledge he has acquired seems to him complete, and he sits, old, weary, and disinterested, among his hoards, looking with lack-lustre eyes on any new treasure that is offered to him for acceptance. The ideal is the man of learning and wide classified experience who is yet able to see and appreciate at its proper value the new fact which does not fit into its appropriate niche. Such are our geniuses. Such was Hunter. Such are Einstein and Fleming.

Broad Principles

Where so many fail, how are we, who wish to do better than the plodders but can never hope to catch the leaders, to make the best use of the experience that life offers to us? Most of us realize that such use as we have made of experience has been due to chance rather than to conscious planning on our part. Most of us cherish the belief that

*Hunterian Oration (abridged) delivered to the Hunterian Society on March 7. The full text will appear in the Society's *Transactions*.

were we to start again on a well-designed and documented system we should get much further. We can, however, agree on certain broad principles.

First, we should make our experience as rich and as varied as we can; not hunting sensations, for the conscious search for new stimuli soon deadens the ability to receive any and abolishes that eager scrutiny with which we should examine those fresh experiences that come naturally, but welcoming experiences from whatever source. We should keep our receptors uncovered and sensitive. We should not refuse to see, hear, touch, or taste anything because we have been warned against it or because it comes to us in unpalatable guise.

Secondly, we should examine each fresh experience with careful scrutiny and an open mind. Even though it be one of a group with which we are already well familiar, does this one contain anything new? Does it repeat and confirm the category to which we had already allotted the others, or does it bring some fresh aspect which should impel us to pull the others out of their pigeon-hole and look at them again?

Thirdly, having examined and accepted it we should turn it over more carefully in our minds, appraise it, classify it, and allot it to one of the trays on our mental desk—"action," "pending," or "finished."

Fourthly, in all our use of experience we should jealously preserve our individuality. Each of us is something new in this world. There has never been anything quite like us before and there never will be again; and that "us-ness" is our most precious possession. We must look at the guidance and the knowledge we get from books and from teachers as a help but not as a directive.

Fifthly, we should pause from time to time for a complete spring-cleaning. We should haul out all our treasured stores of experiences, dust them, and stand back and look at them. Are they all worth keeping? Would some of them go better in another place? Do some of the bits that seemed to be disconnected when we put them away fit together now? Where have we got to? How did we get there? What lies on each side of us? How are those faring who are going along the same road? What lies ahead? Is it the right path, or have we reached a turning-point? Whichever is our goal, how do we get there?

Lastly, we should all the time remember that we are at one stage of a journey. So far so good; or is it? A further journey and possibly better things lie ahead. As we travel we must keep a spirit of alert and adventurous inquiry. We must never look on any conclusion as final, but merely as the best we have been able to do with the material we have encountered so far. We must seek Truth, remembering that when we meet her it may be in a guise we do not expect and coming from a quarter we have despised, and when we have found her we must follow her.

Experience and Judgment

What have any of us learned from experience? If we are honest with ourselves we must answer, "Not as much as we should have." Without a lifelong and unflinching honesty with ourselves we can learn nothing. We may dress the shop window as we like, we may develop a sales personality that is convincing to others, but unless our accounts and our stock-taking are entirely honest we shall finish as cheapjacks. The greatest of the men before us said, "The art of Medicine is long and time is fleeting. Experience is fallacious and judgment difficult." But with experience, carefully recorded and sorted, judgment will come.

Experience properly used gives us a set of standards which fresh experiences can be judged. We learn to size up our patients quickly and fairly accurately as human beings—if they are genuine, self-dramatizers, or humbugs; if they are brave or timid, if they are minimizers or exaggerators, if they are concealing something or merely nervous; and in the light of this assessment we are able to apply a correcting ratio to the symptoms they relate that gives them an absolute value in our diagnostic assessment. We learn to evaluate pain, particularly its severity and its nature, and to construct a scale of our own by which we associate certain pains with certain diseases. We learn that too much pain in too many places is just as much an indication that nothing is seriously wrong as no pain. We learn to know when a patient is ill, when one who has been ill is getting better, or when one who was on the road to recovery has taken a turn for the worse. We come to say by instinct rather than reason, "That child is too ill to be suffering from appendicitis," "That pain is not severe enough for gall-stone colic." We learn what disease to expect at certain ages, in either sex, and in persons of certain appearance, occupation, or bodily habitus. We become so familiar with all the characters of common complaints that a single unfamiliar feature strikes a warning note without our having had recourse to the intellectual process of reasoning.

Physical Signs

We learn to use physical signs, first by rule of thumb, later as conveying certain specific but limited information that is entirely accurate within those limits. Some of the physical signs that were drilled into us as students have no more value than in repeating an obvious fact in alternative and less simple language. All the eponymous signs linked with the exophthalmos of Graves's disease, Stellwag's sign, von Graefe's sign, Moebius's sign, tell us nothing except that the patient is pop-eyed, a fact we already know. Before any of those signs are present the experienced eye can detect an early exophthalmos in a slight puffiness of the upper lid that separates the appearance of the patient from that of the many thousand normal men and women whom we observe daily with no more than a casual glance in the bus and the tube. More important than the names of these buried worthies and the elicitation of their signs is the establishment, without leading questions, that the eyes have, in fact, become more prominent. This can be done by asking if friends have remarked on any change in her appearance, or by looking at a photograph taken before the illness started. The fact that a tumour in the flank can be pushed between a hand in front and one in the loin does not necessarily mean that the tumour is renal; all it tells us is that the tumour and the kidney move as one. In most cases a tumour that gives this sign is one arising in the kidney, but I have recently seen a large mucocele of the gall-bladder and a cystadenoma of the head of the pancreas give the same sign.

We must regard the rules of diagnosis with the same critical impartiality. Courvoisier's law, that in obstruction of the common bile duct by stone dilatation of the gall-bladder is rare while in obstruction due to other causes it is common, is nearly always reliable, but Courvoisier's explanation of his law, that in cholelithiasis the gall-bladder cannot distend because it is fibrosed, is rubbish. The gall-bladder full of stones is often normal in appearance, concentrating power, and microscopical structure, and if the stone obstructs the cystic rather than the common duct it can distend to the most enormous size. In any case fibrous tissue, however dense, becomes plastic when it is inflamed, and in the presence of low-grade infection even the toughest

fibrous structures in the body, the capsule of the hip-joint and the atlanto-occipital ligaments, can stretch. The gall-bladder in common-duct obstruction by stone does not dilate, because the obstruction is partial and intermittent.

We learn by experience the simple truth that our task is to treat the patient and not the disease, that very often the disease that is so obvious to us is not the trouble that is worrying the patient, or perhaps that it is just part, and not necessarily the most important part, of a general derangement of function. The disproportion between the lesion and the general health of the patient in cancer is a matter of constant wonder to the observant doctor. Often we see a patient on the cemetery side of 50 whose sallow complexion and rapid loss of weight and strength tell the unmistakable story of malignancy, yet we find nothing until a routine radiograph shows a small carcinoma of the lung. Yet again we see a man or woman with advanced cancer in a state of rude and robust health.

The temptation to treat a clamant lesion is almost irresistible, particularly to the surgeon.

A public-school boy was recently sent to me for internal derangement of the knee. He could produce a crack like a pistol-shot from both knees by kneeling down and then bending forwards. I could reproduce the same crack in a muffled form, and found it came from the posterior horn of the internal cartilage, and not, as I expected, from the external one. It was very tempting to suggest bilateral meniscectomy. But these cartilages, though they cracked, never locked his knees; though they were abnormally mobile they were not dislocated. He had a history of asthma and fainting attacks and a pronounced cardiac arrythmia, and his knee noises were part of a general locomotor atony that was obvious in a laxity of all his joints and that would have been made worse by meniscectomy at this stage. He required careful observation and nursing through the hazards of adolescence by a wise physician, with surgical intervention as a possible side issue in the future.

During the summer a lady of 73 came to Guy's with veins the diameter of a fountain-pen running their tortuous course from the groin to the axilla on each side, but not approaching the umbilicus. She clearly had obstruction of the inferior vena cava. In a search for the cause of this obstruction I asked for a barium meal, which showed the largest duodenal diverticulum ever recorded, a cavity the size of a tennis ball full of air and bismuth. I admitted her for laparotomy, but, fortunately for me and for her, I was served by a registrar who is wiser than I. "Why operate?" he said. "The lady has an obliterated inferior vena cava, but that is a historic event; her compensation is complete, she has no oedema of the legs, and her renal veins are not involved. She has an enormous diverticulum, but that is no more than a show-ground exhibit; it may originally have had something to do with the thrombosis, but it is now symptomless and harmless. She is as fit as any woman of her age, fitter than most." So we sent her out, with strict instructions to come again to Guy's if she felt ill, for though her lesions may not need operation they certainly need preservation for posterity.

War Experiences

War is the winnowing-ground of experience. During the recent war we learned much of the fundamental problems of injury and infection. We also had the opportunity, never offered in peacetime, of studying the common ailments in significant numbers. In this way we learned some things that are surprising, even shattering. We learned that non-specific epididymitis, which is barely mentioned in text-books, is eight times as common as gonococcal epididymitis and 28 times as common as tuberculous epididymitis. We learned that stress fractures, peacetime rarities, become quite common when adolescents are suddenly called from sedentary jobs to strenuous exercise. We learned that the average operation for the repair of an inguinal hernia in a young man, performed by the average British surgeon in the average British hospital, has a recurrence rate of 20%, and that three-quarters of the recurrences take place in the first six months. We learned that the treatment of varicose veins in this country is not much above that of the African witch doctor. The recruit seen to have visible veins on the lower limb was sent automatically to a vein clinic, automatically transferred to hospital, and automatically treated by the method in vogue at the moment, just as a pig that walks up the ramp of a Chicago factory is pretty sure to come out the other end as two hams, two sides of bacon, and several pounds of sausage.

I and my fellow consultants came to two firm conclusions—that the presence of visible veins along the saphenous system or even of mild aching in hot weather after long standing is not necessarily an indication for treatment, and that the injection of sclerosing substances has no place as the sole or as the primary treatment of varicose veins. I personally would discourage the injection of varicose veins at any stage. They should either be left alone or be treated by high saphenous ligation, a safe but no means simple operation that is nearly as badly done to-day as is that for hernia. The communications between the superficial and the deep veins must also be closed. This may be done by several methods, only one of which is really reprehensible—retrograde injection of sclerosing solutions through a ureteric catheter. I know of two deaths that have followed this procedure. I have also seen a young officer changed thereby from a good rugby threequarter to an oedematous invalid.

The Hollow Needle

This needle has been a mixed blessing. It must bear the responsibility for spinal anaesthesia, and for a number of procedures that substitute blind chemical destruction for clean anatomical removal, such as the injection treatment of veins, haemorrhoids, herniae, hydroceles, ganglia, bursae, and other local swellings. On the other hand, it has allowed the intravenous administration of fluids—a method that may be life-saving, but one that is greatly misused to-day. Some people never seem able to allow their patients to use the channels designed by nature to receive nourishment and to evacuate waste. Food and fluids given by the alimentary canal allow the tissues to select and keep what they want, and to reject what is harmful or surplus to requirements. Fluids given intravenously by-pass all the defences set up by the body to protect itself against excess of any constituent, against bacterial entry, against thermal, chemical, or physical damage; they give the patient what the surgeon thinks his tissues need and what they are dammed well going to get. Nearly all drips set up at the start of an operation are not merely unnecessary but harmful. At least half of the drips set up afterwards are an automatic routine or an assurance against worry rather than a considered form of therapy.

Experience and Wisdom

But I would return to my main theme, that from experience we should derive wisdom. Let us remember that experience is never finished and wisdom is never complete; that we are always more likely to meet the common than the unusual, but that what appears at first to be a simple and familiar clinical problem may yet be something we have never met, even something hitherto unrecorded; that no problem is so straightforward that it does not need careful study, or so difficult that some solution will not appear if we seek steadfastly.

As a surgeon gets older he tends to accumulate the rarities, the difficult decisions, the doubtful issues that his colleagues are only too pleased to pass on. I will mention a few that I have had in the past year.

An old man came to hospital with vague indigestion. An indefinite swelling could be felt on the left of his abdomen. A barium meal showed that the whole of his alimentary canal was to the right of the vertebral column, indicating that it was displaced by a retroperitoneal tumour. An intravenous pyelogram showed two renal pelves on the same side of the abdomen. For a moment I jumped at the diagnosis of a fused kidney, till I realized that the two pelves were not on the side of the swelling but on the opposite side. Operation disclosed a large retroperitoneal lipoma, extending from the pelvic floor to the diaphragm and from the flank to the midline. It was removed with little difficulty and not much bleeding, and was found to weigh 14 lb. (6.35 kg.).

Another man presented with indigestion, wasting, and glycosuria. Radiographs showed that he had a chain of large stones in his pancreatic duct. I could get no advice from books or from my friends how such a problem should be tackled, but I remembered how Roscoe Graham had learned that even a small adenoma could be felt in the head of the pancreas if the pancreas and duodenum were lifted together off the right kidney and palpated between finger and thumb. When I did this I was able to push the stones towards the ampulla of Vater and remove them through the duodenum.

Even the simplest case may be more complex than it looks.

A man arrived at Guy's complaining of a small sinus in the right iliac fossa but otherwise perfectly well. The students immediately suggested actinomycosis, but all of us were astonished to find that lipiodol injected into the sinus outlined all the burrows of a honeycombed liver and then passed through the diaphragm to give a perfect bronchogram.

On the other hand, a case that seems to be desperate may turn out to be quite trivial.

A lady of 50 had been known to have a duodeno-colic fistula since she was 18. Such a lesion is extremely rare, but repeated radiographs had shown that it was, in fact, the cause of the recurring attacks of postprandial diarrhoea from which she had suffered. Between attacks she enjoyed excellent health, and concurred with the advice of her medical attendant that the only risk she ran was that of falling into the hands of a surgeon. However, at 50 an attack that started in the usual way went on to steady deterioration. Her diarrhoea became more profuse at every meal, and finally the stools contained almost unaltered food. She lost weight rapidly.

When I saw her she was a skeleton. Three days later she had lost another 4 lb. (1.8 kg.) and weighed 5 st. 2 lb. (32.66 kg.). Operation, which I had wished to postpone till she got into better shape, had to be undertaken as an emergency. I expected, from the recent history, to find that an old fistula had become carcinomatous. Actually I found a little tube like a section of appendix joining the third part of the duodenum to the back of the ascending colon. A snip with scissors and two purse-string sutures, and the job was finished. A collection of calcareous lumps showed that the original fistula had been caused by a caseating tuberculous gland opening simultaneously into the two viscera; recent ptosis had distorted and blocked the duodenum distal to it.

Surgery of Cancer

In much of major surgery the surgeon knows the size of the job he has to undertake and the strength of his material. By forethought and preparation he can often simplify the task and fortify the material, and if he finishes with those two requirements of a successful operation, a job well done and a live patient, he can look forward to lasting success. In the surgery of cancer, which forms such a large part of his work, he is in the dark. He can assess the size and site of such metastases as are visible, palpable, or radiologically demonstrable, but he cannot even guess whether malignant cells have already got by the lymph stream to further or aberrant glands or by the blood stream to distant parts of the body. Such cells, if they are few in number, will be undetectable by any means, and they may not declare themselves for years.

In 1937 I performed a conservative resection for a rectal carcinoma in a woman of 50. Throughout the war she lived happily and functioned normally. In November, 1945, she developed jaundice, and sank rapidly. She died in January, 1946, nearly ten years after her resection, believing she had gall-stones. The metastases which killed her must already have been present but impalpable at my original operation.

In many cases, particularly when no alternative method of treatment is available—and this applies to all cancers of the alimentary tract—the attempt must be made to eradicate the disease. Operation may seem a desperate chance, but the alternative is no chance at all. The patient is like a man in a burning aeroplane and we are offering him a parachute; to jump is his only chance. A surgeon would have no hesitation in taking the chance were he the patient Dixon, of the Mayo Clinic, used to say, "If ever I get cancer, I am going to a surgeon with good hands and not too much sense."

Cancer surgery is full of disappointments, but it also has its pleasant surprises.

In 1935 I saw a man of 55 with a carcinoma just above the pelvi-rectal junction. At laparotomy I found that the growth was fixed in the pelvis. On freeing it I found that the right wall of the pelvis, the appendix, and the ileum 4 in. (10 cm.) above the caecum were all involved in growth. I removed the appendix, then resected 3 in. (7.5 cm.) of ileum and joined the intestine end to end. I removed the pelvic colon and its mesentery widely down to the upper third of the rectum and did an end-to-end anastomosis, and finally I cut away the peritoneum on the right pelvic wall where it was involved in growth and touched the remaining bare area with the cautery. This patient is as fit to-day as any man of 69, and brought his wife over from Guernsey just before Christmas to have her varicose veins done.

Shortly before I went to Africa in 1940 I saw a woman with a carcinoma at the pelvi-rectal junction in the Southern Hospital, Dartford. At operation I found the whole pelvic floor so widely involved that, though I removed all visible and palpable growth and metastases as widely as I could, I felt that cure was out of the question. I therefore did a Hartmann's operation, leaving the levatores ani and a stump of rectum and anal canal. I saw her again when I came back in 1944. She had returned to her work as a school teacher, had put on weight, and showed no sign of recurrence, so in 1943 Mr. Sol Cohen detached the colostomy and reimplanted it in the stump of her rectum, giving her once again the supreme satisfaction of normal defaecation.

High cure rates and pleasant surprises are usually associated with cancer of the large bowel, but even cancer of the stomach, that most dread form of malignant disease, sometimes belies its reputation.

Just before Christmas, 1946, a proctological friend, who had arranged for a patient to come into the Royal Masonic Hospital for investigation under the provisional diagnosis of carcinoma of the transverse colon, asked me to take charge as he was about to leave for Switzerland. The radiological investigation revealed a large carcinoma of the stomach, invading the transverse colon and its mesentery. I did a high subtotal gastrectomy, removing the stomach in continuity with the middle third of the transverse colon and its mesentery—a satisfactory technical job, but a dismal prognosis. I warned his wife that he was unlikely to live more than three months at most. This summer

he rang me up and asked if he could show me how well he was. Certainly, eighteen months after my hopeless forecast, he looked as well as any man of his age in Europe and showed no sign of cancer. Fortunately he was pleased about it and did not threaten to sue me for £6,000 damages.

Fallacy of Statistics

Such experiences, indeed my whole experience, have left me with profound mistrust of statistics. I have not published mine since I was young and credulous; indeed, I do not know them now unless I ask my registrar to look them up for a particular purpose, and I do not pay any attention to those of others. Personal statistics, as I have said on many occasions, are at the bottom of all unsound teaching: they are either too good to be true or too true to be good.

Those who see statistics in the making are well aware how errors may creep in or be pushed in. Falsification may appear in many ways. The ailing may be transferred to another ward, another block, another hospital, there to die; they may develop complications and be entrusted to the care of a physician and disappear from the surgeon's series; the unsuccessful cases may be indexed under another diagnosis, or appear in the list of operations done by the assistant or the registrar. Quite apart from the temptation to dishonesty, there is, in the keeping and publishing of statistics, an almost insuperable temptation to the surgeon to depart from the only criterion of surgical rectitude—the best interests of the particular patient who is in the ward to-day and will be on the table to-morrow.

The surgeon who never does a severe operation has the fewest deaths, but he saves the fewest lives. The man who limits his operations on hypertension to a small group of young people who respond well to all tests has a wonderfully low death rate and high cure rate, but he passes by all those who need help most. The surgeon who closes up a high proportion of his cancer laparotomies as "inoperable" and reserves his resection for the early growths can show a fine record on paper; how will he himself show up before the recording angel? I personally suspect the man with huge figures and a negligible mortality of being a surgical spiv.

One gastric surgeon surprised the world some years ago by recording 500 gastrectomies for ulcer with 0.6% mortality. Fine! He then reached a total of 1,000 cases with a mortality of 0.6%. Grand! A little later he popped up with 2,000 with a mortality of 0.6%. Marvellous! He now has 3,000 with a mortality of 0.6%. Incredible; especially as the gastrectomies are all done under inhalation anaesthesia with open ether in a clinic where the science of anaesthesia is much where Morton left it. It is clear that to this man, a skilled surgeon, the figure of 0.6% is a symbol, a creed, a banner beneath which he goes into battle. It is his story, and he is going to stick to it. As for myself I shall leave him stuck. The only figures which I find statistically significant are those recorded anonymously and analysed impartially by someone with no personal interest in the verdict. Such are the many statistics published by Colonel Harnett on behalf of the British Empire Cancer Campaign, and Truscott's analysis of twenty years' records of cancer of the breast at the Middlesex Hospital.

I have said, in my Rutherford Morison lecture, that a man is brought into surgery by a love of his fellow men and a sincere wish to help them. As the years go by experience will increase that love and, if he uses it right, will make his power to help more effective. But he must leave it to others to judge in how far he has succeeded.

SEROLOGICAL CLASSIFICATION OF VIRIDANS STREPTOCOCCI FROM SUBACUTE BACTERIAL ENDOCARDITIS, TEETH, AND THROATS

BY

F. R. SELBIE, M.A., M.D., Ch.B., D.Sc., Ph.D.
Reader in Bacteriology, University of London

ROSEMARY D. SIMON, B.Sc., Ph.D.
Assistant Pathologist

AND

R. H. M. ROBINSON, M.R.C.S., L.R.C.P.
Assistant Pathologist

(From the Bland-Sutton Institute of Pathology, Middlesex Hospital)

In a previous report on the treatment of 18 cases of subacute bacterial endocarditis with penicillin (Ward, Meanock, Selbie, and Simon, 1946) it was stated that the biochemical characters of 14 strains of streptococci isolated from these cases indicated that some were similar to *Streptococcus salivarius*, described by Andrewes and Horder (1906) as the most common organism of this type in the mouth and nasopharynx and of frequent occurrence in subacute bacterial endocarditis, while the others were similar to a number of strains isolated by Okell and Elliott (1935) from cases of subacute bacterial endocarditis and from blood cultures in cases of dental sepsis.

It thus appeared likely that our strains of streptococci were of a type often found in subacute bacterial endocarditis and of common occurrence in the region of the mouth. In our further investigation of streptococci from these sources it became evident that biochemical tests were of little value for the classification of the viridans streptococci because of the inconstancy of biochemical reactions within the defined species or groups, as originally pointed out by Andrewes and Horder (1906). We therefore decided that an attempt should be made to classify these streptococci by serological methods.

In this communication it will be shown that when streptococci from cases of subacute bacterial endocarditis are tested with a number of antisera prepared by injecting rabbits with selected strains the reactions so obtained form a pattern on which a serological classification can be based. It will also be shown that streptococci from throat and teeth also react with these antisera to form a similar pattern, indicating a close relationship between the streptococci of subacute bacterial endocarditis and those commonly found in the region of the mouth. Some data are also presented on the relationship between streptococci isolated at different stages in several cases of subacute bacterial endocarditis.

Material and Methods

The investigation was based on 28 strains of streptococci isolated during the past three years at the Middlesex Hospital from 19 cases of subacute bacterial endocarditis and one case in which this condition was suspected, and two cultures of a strain of "streptococcus s.b.e." (Loewe, Plummer, Niven, and Sherman, 1946)—one from a case of subacute bacterial endocarditis and one of the same strain after passage through a rabbit—which were provided by Dr. Erna Altüre-Werber, of the Jewish Hospital, Brooklyn, N.Y. When the work was sufficiently advanced to show that these streptococci and similar streptococci from the throat, teeth, and other sources could be classified

serologically, an examination was made of three further collections of streptococci from cases of subacute bacterial endocarditis. The first of these, consisting of 39 strains from 30 cases, was supplied by Professor J. W. McLeod, of Leeds; the second, consisting of 14 strains from 13 cases at St. Bartholomew's Hospital, London, was supplied by Professor L. P. Garrod; and the third, consisting of 14 strains from 13 cases at St. Mary's Hospital, London, was supplied by Sir Alexander Fleming.

Streptococci from the throat and teeth were also investigated to see how far they could be correlated with the endocarditis strains. The 52 throat strains used were isolated from throat swabs taken by Dr. W. J. L. Sladen from 21 members of the Falkland Islands Dependencies Survey in November, 1947, immediately before the expedition sailed for the Antarctic. Of the 51 strains from teeth 15 were isolated from teeth extracted from four endocarditis cases under the care of Mr. J. W. Schofield and 36 were obtained during routine extractions in 18 cases under the care of Mr. A. L. Packham; 32 of the latter were isolated from the apices of extracted teeth and four from the blood stream of three patients immediately after extraction. Ten other strains of viridans streptococci were examined—three from specimens of sputum, four from abscesses, one from urine, and two from blood cultures in cases in which subacute bacterial endocarditis was suspected but not established.

After isolation and verification of the purity of the cultures the streptococci were transferred to tryptic digest broth with 10% horse blood, incubated overnight, and stored at 4° C. for periods up to six months.

Serological Tests

Preparation of Antisera.—The methods for producing antisera were essentially those used by Lancefield (1933). The immunizing antigen was prepared from 15 ml. of an 18-hour culture of streptococci in 1% glucose digest broth; the culture was centrifuged and the deposit of streptococci was resuspended in 15 ml. of normal saline. The antigen, which was kept at 4° C. when not in use, was injected intravenously into a rabbit in 1-ml. amounts daily for six days. The rabbit was then rested for eight days and given a second course of six daily injections with a fresh preparation of antigen followed by a rest period of eight days. This procedure was repeated until the serum developed enough antibody to give a satisfactory precipitin reaction with the homologous organism. The rabbit was then bled from the carotid artery or by cardiac puncture and the separated serum, with the addition of merthiolate to give a concentration of 1 in 15,000, was kept frozen in the refrigerator.

Untreated streptococci were at first used for immunization and produced good antisera in two rabbits, but several rabbits died with the lesions of bacterial endocarditis after one or two courses, so that subsequent antigens were treated either by heating at 60° C. for 30 minutes or by the addition of formalin to give a concentration of 0.2%. In some cases antisera giving a wider range of reactions were produced by the injection of antigen prepared from a strain after it had been grown for several subcultures in the presence of its homologous antiserum, a method that was used by Lancefield (1940) to produce variation in streptococci.

By these methods a total of 28 antisera were prepared against eight strains of streptococci isolated from cases of subacute bacterial endocarditis at the Middlesex Hospital, one strain of the American "streptococcus s.b.e." (No. 2) and one (No. 30) from a suspected case of subacute bacterial endocarditis. Twenty antisera were used for classification, comprising two (Nos. 2 and 3) produced by the injection of untreated streptococci, two (Nos. 1 and 16) produced by the injection of streptococci treated with formalin, and 16 prepared against four streptococci (Nos. 5, 8, 10, and 30). Each of these four streptococci was used to produce four antisera—two by the injection of heat-treated and formolized organisms and two by the same procedures after growth of the streptococcus in its own antiserum. In the classification of our streptococci shown in Table I the

TABLE I.—*Classification of Streptococci from Subacute Bacterial Endocarditis, Throats, Teeth, and Other Sources by Precipitin Reactions with Antisera*

Group	No. of Strains		Reactions with Antisera							
			5	30	8	3	16	2	1	10

		5	−	+	−	1	−	−	1	+
		7	−	+	−	−	−	−	−	−

The streptococci are classified into five groups each containing three series of strains, in each of which the reactions with the appropriate antisera are indicated thus: + = all strains positive; − = all strains negative; numeral = number of strains positive.

reactions indicated as positive under antisera Nos. 5, 8, 10, and 30 represent positive reactions with any or all of the four antisera prepared against each streptococcus.

Preparation of Extracts of Streptococci.—The method used for the preparation of extracts of streptococci for precipitin tests was the formamide method described by Fuller (1938) for the extraction of polysaccharides and destruction of protein substances.

Precipitin Tests.—The method used for the precipitin test followed that of Lancefield (1933), 0.1 ml. of streptococcal extract being layered above 0.1 ml. of antiserum in a 4 by 0.5-cm. tube. In positive reactions a precipitate at the interface usually formed within 10 minutes, but in some cases there was a delay of up to 30 minutes when the final reading was made. A diffuse flocculation was sometimes observed, but this type of reaction was ignored, as it could not be reproduced and was therefore obviously not specific.

Biochemical Tests

In the fermentation tests the test reagents were purified and used at a concentration of 1% in 1/5 strength infusion broth to which was added 1% bactopeptone, 0.5% NaCl, 2% horse serum, and phenol red as indicator. The results were finally read after incubation for three days at 37° C. Starch-splitting was tested by a plate method following that described by Andrewes (1930) and Hodgson, Heggie, and Sutherland (1943). Bile resistance was tested by the method of Belenky and Popowa (1929) on 5% blood agar with 40% bile prepared from "difco" dried ox bile.

Results of Serological Tests

Positive precipitin reactions to our antisera have been obtained with 181 of the 209 strains of streptococci examined. These positive reactions are tabulated in Table I, where it will be seen that the streptococci are classified according to their reactions with groups of antisera. In

the first group of streptococci are 32 strains which react only with members of the first group of four antisera. In Group Ia are 41 strains reacting mainly with the same four antisera but having side-reactions with other antisera but not No. 16. Group II consists of 28 strains which react only with members of the second group of three antisera, while in Group IIa are 55 strains which react mainly with the same three antisera but have side-reactions with other sera. In Group III are 25 strains which react with antisera 30 and 10, only eight strains having side-reactions with other antisera.

The results obtained with all the streptococci are shown in Table II, which also includes details of the classification

of streptococci from different sources. It will be seen that we have succeeded in classifying all 27 strains from cases of subacute bacterial endocarditis at the Middlesex Hospital and 61 of the remaining 69 endocarditis strains. The 79 endocarditis strains in our serological groups are fairly evenly distributed in the five groups, but there is a preponderance of Group I streptococci in the Leeds collection and of Group II and IIa in the strains from St. Bartholomew's Hospital. The 17 endocarditis streptococci which do not fall into our classification consist of nine strains reacting with Lancefield group antisera and eight with which we have failed to obtain any reaction with the antisera at our disposal.

It is also shown in Table II that 94 of the 103 strains of streptococci from teeth and throats have been classified with our antisera. There is no difference in distribution within the five groups between the strains from these two sources, in spite of the fact that only streptococci showing α-haemolysis on blood agar were selected from cultures of teeth, whereas the streptococci from throats included 13 strains producing no change in blood agar. The distribution of the streptococci from teeth and throats in the five groups, unlike that of the endocarditis strains, is uneven, in that 38 strains, or over one-third, are found in Group IIa and only nine, or about one-tenth, in Group III. The proportion of streptococci from teeth and throats not falling within our classification is even smaller than in the case of the endocarditis strains, there being only nine such strains, three of which react with Lancefield Group D antiserum.

Of the 10 streptococci examined from other sources, four belong to Group IIa, four are distributed among the four other groups, and two do not react with any of the antisera at our disposal.

Regarding the relationship of the streptococci falling within our serological classification to streptococci of the Lancefield groups, we have found cross-reactions with only one streptococcus, No. 30, a strain which was not associated with subacute bacterial endocarditis. This streptococcus is heat-resistant, ferments mannitol, and reacts with Lancefield Group D antiserum, but it also reacts with five of our antisera, Nos. 5, 30, 8, 3, and 10 (Table I), and is thus a typical member of our Group Ia. Three of the antisera prepared against this streptococcus react with only a few streptococci and not with any of our Lancefield Group D streptococci, but the other antiserum, prepared after growing the streptococcus in its own antiserum, reacts with about half our strains and also with five of our eight Lancefield Group D streptococci.

Results of Biochemical Tests

The results of some of the biochemical tests on the streptococci falling into our classification are shown in Table III. All strains ferment dextrose and sucrose. Only

TABLE III.—*Biochemical Reactions*

	Percentage of Strains Giving Positive Reactions in Group					No Reaction
	I	Ia	II	IIa	III	
Fermentation of:						
Lactose	71	79	90	71	76	70
Inulin	16	7	4	7	16	14
Raffinose	37	38	36	49	44	42

No. of strains in each group	32	41	28	55	25	16

one strain, No. 30, which has already been mentioned, ferments mannitol. Fermentation of sorbitol, resistance to a temperature of 60° C. for 30 minutes, growth at 45° C., or growth in 6.5% of sodium chloride are found in only a few strains, which are evenly distributed in the five serological groups. All except three strains produce clot and acid in litmus milk and clot in milk to which 0.1% methylene blue has been added, although it has been stated by Sherman and his co-workers that all known streptococci seem to be inhibited by this concentration of methylene blue except the members of the lactic and enteric groups (Sherman, 1937; Sherman, Stark, and Mauer, 1937).

The results in Table III show some correlation between the biochemical reactions and the serological classification of our streptococci. In Groups I and Ia a relatively high proportion of the strains ferment salicin and trehalose, whereas comparatively few strains in Group II ferment these substances. In Group II also there are only two strains that split starch and only one capable of growing on 40% bile blood agar, whereas a moderate proportion of the strains in the other groups respond to these tests. In Group IIa the proportion of positive reactions is intermediate between those in Group II and Groups I and Ia, thus showing a correlation with the serological characterization of Group IIa by its side-reactions with the antisera determining Groups I and Ia. In Group III there is a moderate proportion of positive reactions to all the tests shown in Table III, with a higher proportion of strains capable of splitting starch than in the other groups. The streptococci not reacting with any antisera do not show any marked difference from the other groups.

Streptococci in Relapses of Subacute Bacterial Endocarditis

The properties of streptococci isolated at different times from 11 cases of subacute bacterial endocarditis are shown

* Reference to case No. in communication of Ward, Meanock, Selbie, and Simon (1946).

in Table IV. In all these cases, with the exception of Case A, the second strain has been isolated during a relapse after treatment with penicillin. In eight cases only two strains have been examined, and in four of these cases both strains are of the same serological group, while in the other four cases the two strains are closely related, one belonging to a group and the other to the corresponding subgroup. In Case D the primary strain, the relapse strain, and four strains isolated at necropsy more than two years later—three from vegetative lesions in the heart and one from the spleen—all belong to Group I or its subgroup, Group Ia. In Case J the primary strain and the first two strains isolated during relapse are all of Group I, but the two later strains belong to Groups IIa and III, although all five strains react with our antiserum 5.

In all the nine cases of relapse that have been mentioned the serological properties of the streptococcus first isolated after penicillin treatment are so similar to those of the initial strain that it would seem that recrudescence of the original infection is a much more frequent cause of relapse than reinfection with another streptococcus. That reinfection does occur, however, is well shown by Case K, in which the second infecting organism is a Lancefield Group D streptococcus presumably derived from an abscess in the buttock from which a *Streptococcus faecalis* was isolated.

The biochemical properties of these streptococci, also shown in Table IV, largely confirm the serological findings. Of the nine cases in which there is a close serological relationship between original and relapse strains, six show identical biochemical reactions or a difference in only one test and two show only two differences, both in the direction of negative to positive, while only in Case H are there more than two differences or differences in both directions.

Distribution of Serological Groups in Teeth and Throats

In cases in which more than one streptococcus has been examined from the teeth of one patient it has been usual to find streptococci of different serological groups. Thus, of 11 strains isolated from seven extracted teeth from a case of subacute bacterial endocarditis (Case C, Table IV) nine are distributed in all our five groups and two are the only strains from teeth in our collection that do not react with any of the antisera at our disposal. The four strains that we have isolated from the blood stream immediately after the extraction of teeth are also a representative series, two from one patient being of Groups I and Ia and two from two patients being of Groups II and IIa. Our findings are similar to the 48 streptococci isolated from the throat in the 17 cases in which more than one streptococcus has been examined. In only one of these instances is one serological type alone represented, and in only two are there only streptococci of a group and its corresponding subgroup.

The limited data so far available thus show that there is no tendency for the streptococci of the teeth or throat in a single person to belong to one serological group.

Endocarditis Streptococci in Relation to Response to Penicillin Treatment

In Table V is shown the relationship between the response to treatment with penicillin and the sensitivity to penicillin and serological group of the streptococci isolated before penicillin treatment in the 59 cases in which the necessary information is available. Response to treatment is assessed as bad when the patient died without control of the infection. This table has been examined by Mr. T. E. Cowan, F.C.I.S., F.R.S.S., records officer, Middlesex Hospital, who states: "I agree that the main point brought out is that in total the proportion of bad responses to penicillin treatment increases with resistance of the infecting organism to penicillin. The regularity of the arithmetical progression is sufficient to justify this view. I do not think it can be taken that the classification according to the serological group of the infecting streptococci shows a correlation between the serological group and the response to infection; the numbers examined are too small to be statistically significant."

TABLE V.—*Relationship of Result of Penicillin Treatment of 59 Cases of Subacute Bacterial Endocarditis to Penicillin Sensitivity and Serological Group of Streptococcus Isolated Before Treatment. Streptococci Reacting with Lancefield Group Antisera Are Not Included*

Discussion

The difficulties presented by the complex antigenic structure of the viridans streptococci have hitherto prevented an

adequate classification of these organisms by serological methods. The situation is well exemplified by the observations of Gordon (1922), who found that 16 strains of *Str. salivarius* represented at least 12 different types, whereas 125 of 131 strains of *Str. pyogenes* were of the same serological type. We also have found that the viridans streptococci are a heterogeneous group of organisms, but we have succeeded in making a serological classification by using antisera with a wide range of action and basing our classification on the reactions obtained with groups of these antisera.

In this way we have been able to classify 181 (92%) of the 197 strains of our collection that do not belong to the Lancefield groups into five groups containing 32, 41, 28, 55, and 25 strains respectively. This represents a higher degree of success than that attained by Solowey (1942), who, with a similar collection of 205 strains of viridans streptococci, classified 136 strains (66%) into 14 groups, 11 of which contained only one to five strains each. It is noteworthy that Solowey's three main groups, comprising 77, 23, and 13 strains, were based on reactions with groups of seven, five, and two antisera respectively, whereas the other smaller groups were determined by reactions with single antisera.

It would thus seem in the present state of our knowledge that these streptococci are amenable to classification only by studying their reactions to groups of antisera with a wide range of action. It would also appear necessary to prepare bacterial extracts for the precipitin test by the formamide method of Fuller (1938), which in our experience provides a much more efficient antigen than the acid extraction method of Lancefield (1933), which was used by Solowey (1942).

We have shown that viridans streptococci isolated from cases of subacute bacterial endocarditis have a distribution in our serological groups similar to that found in streptococci from teeth and normal throats. The same observation has been made by Solowey (1942) on the basis of her serological classification, and we agree with her that no distinction can be made between the viridans streptococci derived from these different sources. It would, however, appear from our results that streptococci of Group IIa, the largest group in streptococci from teeth and throats, have less tendency to produce subacute bacterial endocarditis than the streptococci of the other four groups. These observations nevertheless give further support to the view we have previously expressed in common with others that the viridans streptococci of subacute bacterial endocarditis come from the region of the mouth (Ward, Meanock, Selbie, and Simon, 1946). In the earlier communication we noted the association between dental sepsis and the initiation of the symptoms of subacute bacterial endocarditis, and here we have not only confirmed the finding of Okell and Elliott (1935) that viridans streptococci may escape into the blood stream during dental extraction but have also found that these streptococci belong to the same serological groups as those of subacute bacterial endocarditis.

It is not, however, generally agreed that the great majority of the streptococci of subacute bacterial endocarditis are derived from the region of the mouth. It has recently been reported from America that about one-third of the streptococci isolated from cases of subacute bacterial endocarditis belong to a hitherto undescribed group of the viridans type, usually referred to as "streptococcus s.b.e.," which is not a normal inhabitant of the human mouth and has been given the name of "*Streptococcus sanguis*" (Loewe, Plummer, Niven, and Sherman, 1946; White and Niven, 1946).

The two strains of "streptococcus s.b.e." that we have examined have few of the biochemical properties ascribed to this group by the American authors, but in this respect are very similar to other streptococci of Groups II and IIa to which they belong in our classification. On the other hand, our findings with an antiserum we have produced with one of our strains of "streptococcus s.b.e." (No. 2), which reacts with about 27% of our endocarditis strains, are similar to those of Schneierson (1948), who, working with American strains from cases of subacute bacterial endocarditis, found that 23% of a total of 34 strains gave a positive precipitin reaction with an antiserum prepared against a strain of "streptococcus s.b.e." Washburn, White, and Niven (1946) have described two serological types of "streptococcus s.b.e.," but have also found cross-reactions with other types of viridans streptococci.

It would thus seem that further clarification is necessary before it is possible to assign the position of "streptococcus s.b.e." in relation to the other viridans streptococci. This is a question of some importance, because this group of streptococci is regarded as being somewhat more resistant to penicillin than the other viridans streptococci. In our experience, however, there appears to be no significant correlation between the serological characters of the streptococci of subacute bacterial endocarditis and penicillin sensitivity or response of the case to penicillin treatment (Table V) except for the streptococci of Lancefield Group D, which are highly resistant to penicillin.

Another question that has recently been raised concerns the position of *Str. salivarius*, which was originally described by Andrewes and Horder (1906) as the most common streptococcus in the human throat and of frequent occurrence in subacute bacterial endocarditis. Sherman, Niven, and Smiley (1943) have now assigned this name to a streptococcus which is found in the human throat but has never been isolated from cases of subacute bacterial endocarditis and is identified by the production of large mucoid colonies on sucrose agar. We have confirmed that streptococci of this type are present in small numbers in a high proportion of normal throats, and that they form a homologous group in both their biochemical and their serological characters. They form a distinct group of streptococci, differing widely from all the streptococci that we have isolated from cases of subacute bacterial endocarditis and from the streptococci that are encountered in cultures obtained from teeth and throat by the usual routine methods. We are, however, of the view that, although *Str. salivarius* is an ill-defined species, its definition should remain sufficiently wide to include streptococci of the type originally observed by Andrewes and Horder (1906) and not be restricted to streptococci not usually met with either in the examination of throat swabs by routine bacteriological methods or in cases of subacute bacterial endocarditis.

Our finding that streptococci isolated during relapses after penicillin treatment in subacute bacterial endocarditis are usually similar to the strains isolated before treatment is of some clinical importance in that it indicates that relapses are generally due to a recrudescence of the original infection and not to reinfection. It would seem, therefore, that relapses after penicillin therapy are usually due to inadequate treatment. That the dosage of penicillin in many cases may have been inadequate in relation to the resistance of the infecting organism is indicated by the findings in Table V, in which a bad response to penicillin treatment is correlated in 11 of 29 cases with a coefficient of resistance of 1.3 to 6 and in only three of 28 cases with a coefficient of resistance of 1 or less. It can therefore be expected that a

general increase in dosage from half a million units of penicillin a day for 28 days to two million units a day for six weeks, as recently recommended by Christie (1949), will improve the results of penicillin treatment.

There are, however, cases in which relapse cannot be ascribed to undue resistance of the infecting streptococcus to penicillin, and it may be that the causal organisms are so protected by dense vegetative lesions that they are inaccessible to the action of penicillin. It is now accepted that in conditions where the sources of infection are accessible the chances of a recrudescence of the infection can be greatly reduced by the removal of infected and avascular tissue after infection has been brought under control by penicillin (Hudson, Meanock, McIntosh, and Selbie, 1946). It is thus possible that surgery may yet provide a solution to the problem of persistent relapses after penicillin therapy in subacute bacterial endocarditis by evolving methods for the removal of the infected vegetations and the reconstruction of damaged valves.

Summary

Streptococci of the viridans type from cases of subacute bacterial endocarditis and from normal throats and extracted teeth have been differentiated into five serological groups.

The distribution in the five serological groups of the streptococci from subacute bacterial endocarditis is similar to that of the streptococci from throats and teeth, indicating that the streptococci of subacute bacterial endocarditis are derived from the region of the mouth.

Streptococci isolated during relapses after penicillin treatment in subacute bacterial endocarditis are usually similar in their serological and biochemical characters to the streptococci isolated before treatment, indicating that relapses are generally due to a recrudescence of the original infection and not to reinfection by another streptococcus.

The relationships of "streptococcus s.b.e." and *Str. salivarius*, as described by Sherman and his co-workers, to other members of the viridans group of streptococci are discussed.

We wish to express our thanks to Professor J. W. McLeod and Dr. Betty Dawson, of the School of Medicine, Leeds, to Professor Sir Alexander Fleming, of the Wright-Fleming Institute of Microbiology, St. Mary's Hospital, London, and to Professor L. P. Garrod, of the Pathological Department, St. Bartholomew's Hospital, London, for providing collections of streptococci isolated from cases of subacute bacterial endocarditis; and to Dr. W. J. L. Sladen, of the Falkland Islands Dependencies Survey, for providing throat swabs from normal persons. We also wish to acknowledge our debt to the late Professor James McIntosh for his unfailing interest and help.

TREATMENT OF EARLY SYPHILIS WITH PENICILLIN COMBINED WITH NEOARSPHENAMINE AND BISMUTH

BY

J. W. EAMES, M.B., Ch.B.

Colonel, late R.A.M.C.; Formerly Adviser in Venereology to the Army

AND

D. H. MILLER, M.B., Ch.B.

Lieutenant, R.A.M.C.

Since the introduction of penicillin for the treatment of syphilis routine standard courses of treatment have been in use in the Army for the treatment of early cases. In 1944 the first scheme of treatment to be used consisted of 2,400,000 units of penicillin in aqueous solution given intramuscularly in 60 divided doses, each of 40,000 units. In 1946 it became obvious from a scrutiny of the records of patients so treated that there was a failure rate of 8% in the first six months (Marshall, 1946).

In consequence, a course which consisted of 4,000,000 units of penicillin in aqueous solution given intramuscularly in divided doses over a period of 12½ days was introduced at certain military hospitals. Also, in view of the fact that Eagle and his co-workers (1946) showed that there was a synergistic action between penicillin and arsenic in the treatment of rabbit syphilis, a standard scheme was introduced at certain other scheduled hospitals in the United Kingdom, consisting of 2,400,000 units of penicillin together with ten daily injections of 0.06 g. of "mapharside." In addition, at one military hospital in the United Kingdom a series of cases of early syphilis was treated by means of a somewhat similar course with the addition of 1 g. of bismuth (Willcox, 1946).

The cumulative relapse rates following treatment by means of the above four schedules were calculated by James, Mackay, and Wright (1948) in a series of 281 cases, using a formula evolved by the Honorary Consultant in Statistics to the Army. By this means it was found that the cumulative relapse rates at twelve months in the case of patients treated with 2,400,000 units of penicillin were 14% for sero-negative primary syphilis, 13% for sero-positive primary syphilis, and 17.5% for secondary syphilis. The results of the other courses of treatment were essentially much the same.

In 1946 reports from the United States had shown that penicillin K was less effective than penicillin G in the treatment of rabbit syphilis, and that commercial penicillin had tended to contain increasing amounts of penicillin K. The Subcommittee on Venereology of the Army Medical and Personnel Research Panel therefore adopted a scheme of treatment by which a total of 4,000,000 units of penicillin was given over a period of ten days, combined with a course of neoarsphenamine and bismuth (Eames, 1948); the addition of the latter conformed to the original suggestion of Harrison (1945). This schedule is the one considered here.

Treatment, Surveillance, and Sources of Material

The treatment was carried out as follows. During an initial period in hospital a course of 4,000,000 units of commercial penicillin (50,000 units in aqueous solution intramuscularly at three-hourly intervals over a period of ten days) was given. On the second, fifth, and ninth days

the patient received an intravenous injection of neoarsphenamine, 0.3 g., 0.45 g., and 0.6 g., respectively, together with an intramuscular injection of 0.2 g. of bismuth (1 ml. injectio bismuthi *B.P.*). On completion of this treatment, and subject to the clinical condition, the patient was returned to full military duty. Out-patient treatment was started seven days after his last injection of arsenic as an in-patient, and consisted of eight weekly injections of 0.6 g. of neoarsphenamine and 0.2 g. of bismuth. Thus the total treatment was 4,000,000 units of penicillin, together with 6.15 g. of neoarsphenamine and 2.2 g. of bismuth.

It is the routine in the Army for all cases of syphilis, after completion of active treatment, to have clinical and serological examinations at two-monthly intervals for six months, quarterly for one year, and six-monthly for a further year. A complete cerebrospinal fluid examination is carried out at the end of the first six months and also during the last six months of this surveillance. Both Wassermann and Kahn tests (qualitative and quantitative) were invariably made at each serological examination in our series of cases.

Nominal rolls of all cases treated at the special treatment centres in the United Kingdom by the schedule described above had been maintained from its inception. Thus it was possible to trace the records of all patients in whom treatment was initiated during the period December, 1946, to March, 1948, by examination of the record cards maintained at the Central Syphilis Register.

Some of the cases on the nominal rolls described above were not suitable for the purposes of this investigation, as those previously treated and cases of congenital, latent, and tertiary syphilis had been included. These were discarded, together with any case in which there was a doubt about the initial classification of the disease. All of the patients were males of military age, the vast majority falling between the ages of 19 and 25. All were suffering from early syphilis—namely, sero-negative primary syphilis, sero-positive primary syphilis, and early secondary syphilis.

In all cases of sero-negative primary syphilis the *Treponema pallidum* had been demonstrated in a scraping taken from the primary lesion and examined by dark-field. All other cases showed a positive serology, and the secondary cases showed such manifestations as a rash and/or mucous patches or condylomata. *Tr. pallidum* was demonstrated in 87% of sero-positive primary cases and in 65% of secondary cases.

The record cards of 1,284 patients were examined, and of these, after discarding those of the patients described above, 1,028 were found to conform to the terms of reference of the survey. The distribution of patients according to the stage of the disease is shown in Table I.

TABLE I.—*Analysis of Cases According to Stage of Disease*

Sero-negative primary	353	(34·6%)
Sero-positive primary	443	(42·9%)
Early secondary	232	(22·5%)
Total	1,028	(100%)

As the form of treatment under survey was not begun until December, 1946, it was possible to consider a maximum follow-up of only 18 months.

Criteria of Efficacious Treatment

In reviewing the results of treatment a patient was considered to have made satisfactory progress, to have relapsed, to have failed to respond to treatment, or to have become reinfected.

A case was regarded as having progressed satisfactorily if it conformed to the following criteria: (i) all lesions of syphilis had healed at the conclusion of treatment and surveillance; (ii) serological tests for syphilis were negative at the end of surveillance; and (iii) the cerebrospinal fluid examination was normal.

Relapse was diagnosed from the presence of fresh clinical manifestations of syphilis from which the *Tr. pallidum* could be isolated, or a change in serology from negative to positive, or abnormal C.S.F. findings. All patients still having a positive serology four months after treatment had ceased were classified as treatment failures, when further treatment was begun.

Patients were classified as "defaulters" at that time when for any reason they ceased to be followed up, or, alternatively, in the case of patients treated during the last months of this investigation, at the stage in which, though satisfactory progress was being made, the survey period closed. Thus a patient completing treatment in December, 1947, would be shown as "defaulting" at nine months if satisfactory progress was made up to September, 1948, as no records would be available after that date (see Table II).

TABLE II.—*Showing "Default" from Surveillance*

	Sero-neg. Primary	Sero-pos. Primary	Secondary	Total
Initial no. of cases examined	353	439	230	1,022
Cases completing all treatment	274	321	159	754
Cases "defaulting" in first 2 months	90	137	70	297
Cases left at beginning of 3rd month	184	183	89	456
"Defaulters" (3–5 months)	37	30	10	77
Cases left at beginning of 5th month	145	152	69	366
"Defaulters" (5–7 months)	29	32	14	75
Cases left at beginning of 7th month	113	113	54	280
	37	38	24	99
	72	69	29	170
	34	30	15	79
Cases left at beginning of 13th month	36	38	14	88
	22	22	7	51
	11	13	7	31
	5	9	5	19
	6	3	1	10
	6	3	1	10

The totals shown as remaining at the beginning of any one month are those making satisfactory progress only.

It is impossible to classify any case defaulting from surveillance before the fourth month of follow-up if the serology remains positive with no clinical signs of relapse. Such were therefore rejected from the pool of data. Thus, of 1,028 patients initially considered only 1,022 could be utilized, as two (0.86%) in the group diagnosed as secondary syphilis and four (0.9%) from the sero-positive primary group had to be rejected.

Results of Therapy and Discussion

Tables II, III, and IV show in crude figures the results of treatment and follow-up of all categories of patients treated. It will be seen that there is an extremely high rate of "default." This was consequent upon the rapid rate of release from the Forces over the period during which this investigation was carried out.

TABLE III.—*Muco-cutaneous Infectious Relapses—Crude Figures*

Months After Treatment	Sero-neg. Primary	Sero-pos. Primary	Secondary	Total
0–2	1	1	0	2
2–4	3	2	0	5
4–6	2	4 (1)	0	6 (1)
6–9	1	0	0	1

12–15	0	1 (1)	0	1 (1)
15–18	0	0	0	0
Total	10	9	0	19

Figures in parentheses denote cases considered to be possible reinfections—e.g., 2 of the 3 at 12 months.

TABLE IV.—*Total Relapses—Crude Figures*

Months After Treatment	Sero-neg. Primary	Sero-pos. Primary	Secondary	Total
0–2	2	2	1	5
2–4	3	3	1	7
4–6	4	6 (1)	1	11 (1)
6–9	2	1	0	3
9–12	3 (2)	3	0	6 (2)
12–15	0	1 (1)	1	2 (1)
15–18	0	0	0	0
Total ..	14	16	4	34

Figures in parentheses denote cases considered to be possible reinfections—e.g., 2 of the 3 at 12 months.

Of the 353 sero-negative primary cases beginning treatment, 14 were considered to have shown unsatisfactory progress: these are analysed in detail in Table V. It will

TABLE V.—*Analysis of Relapses Occurring in Sero-negative Primary Syphilis*

Type of Relapse	No. of Cases					Total Cases
	2 mths	4 mths	6 mths	9 mths	12 mths	
Muco-cutaneous relapse ..		1	1	1		3
Clinically diagnosed as re-infection	1	2	1		2	6
Serological relapse ..	1		1	1	1	4
Asymptomatic neuro-relapse			1			1

be seen that no patient relapsed after the twelfth month, but, in view of the relatively small number of cases remaining (36) at the time, this is not necessarily significant. The one case of asymptomatic neuro-relapse which occurred was diagnosed on an abnormal cerebrospinal fluid found on routine lumbar puncture during the sixth month.

Of the above 14 cases considered to have relapsed six were diagnosed by the clinician concerned as reinfections. In view of the uncertainty of differentiating between relapse and reinfection at the present time, and as the cases did not completely satisfy the criteria of Halley and Wassermann (1928) or Moore (1943), they have been classified as relapses (see Table V). All these cases had been previously sero-negative, in all of them *Tr. pallidum* had been demonstrated in the new lesion, and all gave a history of recent exposure. In only two cases, both occurring one year after treatment ceased, were all Moore's criteria fulfilled (see Table VI),

TABLE VI.—*Application of Moore's Criteria of Reinfection to Cases so Diagnosed Clinically*

Type of Case	Serology Before Possible Reinfn.	Time Since Treatment Ceased	History of Recent Expo-sures	New Site for Primary Sore	Change in Sero-logy	Conclusion

" " "	"	1 year	"	?	Yes	" "
" " "	"	15 mths	"	Yes	"	Poss. reinfn.

but in neither of these was there adequate proof that the new sore occurred in a different lymphatic shed from the original. In these two cases there was a sero-reversal after the appearance of the new sore, and they can therefore be considered to be possible reinfections. In no case, however, was there any record of an infected consort being traced.

Among the 439 cases of sero-positive primary syphilis there were 20 which made unsatisfactory progress. These are analysed in Table VII, from which it will be seen that serological relapse is more common than in sero-negative primary syphilis, and that, for the first time, treatment

TABLE VII.—*Analysis of Relapses and Failures Occurring in Sero-positive Primary Syphilis*

Non-infectious relapse: Serological relapse ..	1	1	2	1	2		7
Treatment failures: Serological fast	4						4

failures (serological-fast cases) appear. Those cases which were in the first instance clinically diagnosed as reinfections are considered in Table VI. Two of these cases fulfil all of Moore's criteria; but again, with the notes available, difficulty arises regarding the exact site of the alleged fresh primary sore.

Thirteen of the patients treated for secondary syphilis failed to show satisfactory progress, nine of these being treatment failures (Table VIII). There were no muco-

TABLE VIII.—*Analysis of Relapses and Failures in Early Secondary Syphilis*

Type of Relapse	No. of Cases						Total Cases
	2 mths	4 mths	6 mths	9 mths	12 mths	15 mths

Treatment failures	9						9

cutaneous relapses in this group of cases, and no case was diagnosed as a reinfection.

Moore (1948) expressed the opinion, which he said was instigated by the statisticians, that in order to avoid getting a false statistical picture it would be unwise, owing to inevitable attrition, to draw conclusions about the effects of treatment in early syphilis without at least a thousand cases to begin with, and that when evaluating such material it was essential to use an actuarial method.

Of the 1,022 cases originally considered suitable, 754 completed the full scheme of treatment, and it is from this number that the cumulative relapse rates are calculated (see Table II). The results can therefore be considered as only approximate. It is impossible to assess the sampling error in the method of calculation used, and towards the latter end of the survey this is not inconsiderable.

An extremely large number of patients were lost to observation during the post-treatment surveillance period owing to release from the Service. In order to allow for this, the cumulative relapse rate (both total and infectious muco-cutaneous) has been calculated from the crude figures shown in Tables II, III, and IV. Treatment failures are not included in the cumulative relapse rates shown, but are considered separately. The method of calculation used by James, Mackay, and Wright (1948) has been utilized.

The total and infectious (muco-cutaneous) cumulative relapse rates are shown in Table IX. Here all those cases diagnosed as reinfections by the clinician concerned are classed as relapses. If the four cases which were possible reinfections (see above) are considered to be in fact such, then the rate is as shown by the figures in parentheses. It will be seen that the total cumulative relapse rate at 18 months is somewhat less for early secondary than for sero-positive primary syphilis. This is a trend which is in accordance with the results of others. For all types of

TABLE IX.—*Analysis of Cumulative Rate of Relapse During Surveillance*

Time	Sero-neg. Primary	Sero-pos. Primary	Secondary	Total
	Infectious (Muco-cutaneous) Relapse Rates			
6 months	3·8%	4·5% (3·8%)	0%	3·3% (3·0%)
12 ,,	10·0% (6·6%)	6·3% (5·6%)	0%	6·6% (5·0%)
18 ,,	10·0% (6·6%)	9·9% (5·6%)	0%	8·2% (5·0%)
	Total Relapse Rate			
6 ,,	5·7%	6·9% (6·2%)	3·6%	5·7% (5·2%)
12 ,,	12·6% (9·3%)	13·0% (12·3%)	3·6%	12·1% (9·3%)
18 ,,	12·6% (9·3%)	16·4% (12·3%)	12·4%*	15·0% (10·8%)

Figures in parentheses show cumulative relapse rates when possible reinfections are accepted as such.
* The sampling error here is considerable in view of the small number of cases involved

cases considered the muco-cutaneous relapse rate, which from a public health point of view is an important yardstick by which to judge the efficacy of treatment, is either 8·2 or 5% at 18 months. The Clinical Co-operative Group figures (Moore, 1943) show that 85% of such relapses occur in the first two years of surveillance after long-term arsenical and bismuth therapy.

Moore (1947), utilizing a total dosage of 2,400,000 units of penicillin, quotes a cumulative relapse rate at 11 months of 15%, and of 21% for a schedule of 2,400,000 units of commercial penicillin with the addition of 320 mg. of arsenoxide (in eight daily injections each of 40 mg.). Reynolds (1948), in considering various schedules of treatment for early syphilis by means of commercial penicillin alone (totals of 4,800,000 units two-hourly for eight days, 4,800,000 units three-hourly for eight days, and 9,600,000 units three-hourly for 15 days in divided doses), gives a combined cumulative relapse rate of 16.43% during the twelfth month of follow-up. At the end of the twelfth month the cumulative relapse rate (total) for the scheme discussed in this paper is either 12.1 or 9.3%, depending, as stated above, on whether certain of the cases diagnosed as reinfections are included as relapses or not. At the end of the eighteenth month these figures are 15 or 10.8%. The cumulative relapse rates thus appear to be at least as satisfactory as, if not superior to, those obtained with the various schemes of treatment reported in the last few years.

Toxic Reactions

It was not always easy to judge from the clinical notes made at the time whether such toxic reactions as were observed were definitely due to penicillin or to arsenic. This is especially the case as regards ninth-day erythema, which tends to occur at about the same time as urticarial reactions due to penicillin. However, in most cases the clinician treating the patient expressed an opinion concerning the causation, and in cases in which there appeared to be a doubt the toxic reaction has been considered as being due to arsenic. In consequence the actual arsenical toxicity rates may in fact be less than those given below.

Reactions due to penicillin, either local or generalized, were rarely recorded. Such cases of penicillin urticaria as were noted responded to treatment, usually with no interruption of the routine antisyphilitic therapy.

There were 33 cases in which the toxic effects occurring were considered to be due to neoarsphenamine. In 28 of these no more arsenical treatment was given to the patient after the toxic reaction; in the remaining five cases treatment was interrupted, but was later resumed. Seventeen cases of arsenical toxicity occurred in the first three weeks of treatment; the remainder showed a fairly even scatter throughout the rest of the period of treatment.

Six cases of jaundice occurred in the series, but, since it is generally accepted that this condition is of infective origin, they are not included in the series of toxic effects considered to be due to neoarsphenamine. Of these six patients, one developed jaundice during the first ten days of treatment, the remaining five at intervals between two and five months after the beginning of treatment.

The following analysis of the 33 reactions caused by neoarsphenamine shows that the vast majority were in the nature of a dermatitis: *Toxico-dermal reactions:* ninth-day reaction, 9 cases; dermatitis, 19; pruritus, 1 case. *Gastro-intestinal reactions:* nausea, 1 case. *Other reactions:* encephalopathy, 1 case; agranulocytosis, 1 case; albuminuria, 1 case.

During the hospital phase of treatment, in addition to the nine cases of ninth-day erythema observed, six patients showed toxic reactions due to arsenic: of these, one developed a punctate dermatitis and treatment was interrupted for a week but was later resumed: in the five others, which included one case diagnosed as arsenical encephalopathy, treatment with neoarsphenamine was discontinued. In five of the nine cases of ninth-day erythema arsenical therapy was also discontinued. During the out-patient phase of treatment toxic reactions occurred in 18 patients, and in all of them treatment with neoarsphenamine was permanently stopped.

There was no fatality among the patients in whom toxic reactions occurred, and in only three cases could there have been considered to be a danger to life. These latter consisted of one case of exfoliative dermatitis, which occurred in a patient with sero-negative primary syphilis 74 days after the onset of treatment; one case of agranulocytosis with angina, which occurred in a patient with sero-negative primary syphilis 23 days after treatment started; and one case of arsenical encephalopathy occurring nine days after the beginning of treatment in a patient with secondary syphilis. All these patients received BAL (OX 217) in the following dosage: 4 ml. four-hourly for three doses on the first and second days of treatment, and daily doses of 4 ml. for the next two to five days.

Since records are complete for the in-patient period of treatment, toxic reactions within the first ten days can be expressed as a percentage of all cases completing hospital treatment. With regard to reactions occurring in the out-patient period of treatment (late toxic reactions), the number of patients completing all treatment and the number "*defaulting*" during the out-patient phase are known. A reasonable estimate of the total number exposed to the risk of toxicity will therefore be the total of those known to have completed treatment, plus half the number of patients "defaulting" during this phase (Table X). With this assumption, for all the patients

TABLE X.—*Crude Figures of Number of Patients Exposed to Toxicity*

	Sero-neg. Primary	Sero-pos. Primary	Secondary	Total
(*a*) No. of patients starting hospital treatment	353	439	230	1,022

(*f*) Total no. of early toxic reactions in which treatment stopped	3	4	2	9
(*g*) No. of toxic reactions in O.P. treatment phase	6	10	3	19

treated, the toxicity rate during the early portion of treatment is 1.37%, and that for the out-patient phase of treatment 2.14%—thus giving an estimated total toxicity rate of 3.51%. In Table XI these figures are broken down according to the stage of disease when first treated.

TABLE XI.—*Analysis of Rates of Toxic Reactions*

	Sero-neg. Primary	Sero-pos. Primary	Secondary	Total
Toxicity rate during hospital phase of treatment	1·41%	1·13%	1·72%	1·37%
Late toxicity rate	1·91%	2·63%	1·54%	2·14%
Overall toxicity rate	3·32%	3·76%	3·26%	3·51%

Summary and Conclusions

An analysis of the results of treatment of 1,028 patients treated for early syphilis, with a schedule consisting of 4,000,000 units of penicillin combined with one course of neoarsphenamine and bismuth, is described.

There was a high rate of "default" from surveillance due to the rapid release of patients from the Service. In order to offset this and to obtain a true statistical picture an actuarial method has been used.

If all patients who were considered by the clinician concerned to have become reinfected were accounted for as relapses, then the total cumulative relapse rate at 18 months was found to be 15% and the cumulative muco-cutaneous infectious relapse rate 8.2%. If four of the ten cases clinically diagnosed as reinfections are accepted as such these relapse rates would be 10.8 and 5% respectively. These results would seem to be more satisfactory than those reported by others using commercial penicillin alone and in combination with mapharside by the semi-intensive method.

Treatment failures (cases showing sero-resistance) were small in number, being 0.9% of sero-positive primary cases and 3.87% of secondary cases.

Toxic reactions were of a very low incidence, occurring in 3.51% of all patients treated, and there were no fatalities.

We are indebted to Brigadier J. Bennett, Director of Medicine and Consulting Physician to the Army, and Brigadier H. T. Findlay, Director of Pathology, for permission to submit this paper for publication, and to the venereologists working at the various treatment centres for their co-operation. Our thanks are also due to Major R. B. Stalbow for his advice in regard to the statistical problems involved.

The current issue of the *Practitioner* is devoted to a review of the first year's working of the National Health Service. All the contributors are anonymous, but there is an editorial assurance that they are outstanding in their own spheres. A physician concludes that "there is no evidence that the health of the nation has benefited from the first year of the National Health Service. On the other hand . . . no great harm has resulted." A surgeon puts forward a number of constructive suggestions, and an obstetrician takes the view that "the field is set for a wonderful experiment which could not fail to yield encouraging and possibly dramatic results." General practitioners put forward their own distinctive views, and two newly qualified practitioners contrast their enhanced material security with certain spiritual doubts.

SEX HORMONE UPSET IN AFRICANS

BY

J. N. P. DAVIES, M.D.

Pathologist, Colonial Medical Service, Uganda; Part-time Lecturer in Pathology, Makerere College Medical School

Only in the last few years has interest begun to be focused on the non-parasitic pathology of Africans. The gaps in our knowledge are so immense that it is extremely unwise to be dogmatic on any point in African pathology. Nevertheless, from the few centres where pathological investigations, and particularly necropsies, are being carried out reports are accumulating which show that there are striking differences between the incidence of various lesions in Africans and in Europeans. These have been reviewed by Lewis (1942) and Gelfand (1948). Owing to the total absence of reliable statistics it is usually very difficult to express these differences, and all figures must be interpreted with great caution. Certain of these differences are explicable on climatic or parasitic grounds, others, such as sickle-cell anaemia, on racial grounds, but the majority still defy explanation.

In this paper I suggest that certain of these so far unexplained differences are explicable on the assumption that, because of the almost universal liver damage, Africans are subject to oestrinization on almost a national scale, or even on a continental scale. As chemical analyses of the urines to ascertain sex hormone excretion have not yet been performed, it is proposed to review the evidence supporting this hypothesis.

Malnutrition in Africans

It has long been known that there is a very high incidence of liver disease in Africans and that cirrhosis is extremely common (Vint, 1931); in fact, in East Africans and in the South African Bantu it has been found to be almost universal (Davies, 1948a, b, c; Gillman and Gillman, 1948). Recently evidence has accumulated which suggests that this liver damage is largely the result of malnutrition, assisted perhaps in certain areas by the effects of parasites (Davies, 1948a, b, c). Owing to malnutrition a fatty liver develops early in childhood and cell accumulations then occur with fibrosis, with or without the deposition of iron. Cirrhosis of the liver of a Laennec type often develops even in young children. In those less affected who survive, the liver is permanently marked and often functionally upset.

After childhood is passed recurrent episodes of malnutrition or chronic infections will precipitate further attacks, so that these patients present, both clinically and pathologically, a state somewhat similar to that seen in young children. Other causes of liver damage, such as infectious hepatitis and post-arsenical jaundice, are also common in Africa, and there is reason to suppose that nutritional hepatic necrosis occurs in Africans as it is suspected to do in Ceylon (Fernando, Medonza, and Rajasuriya, 1948). Clinically, Trowell (1946) has found that this malnutritional syndrome, kwashiorkor, is extremely common in African children, and, owing to the prolonged period of breast-feeding and the absence of a proper weaning period, few African children escape without at least a minor attack of the condition. This clinical observation is fully in accord with the pathological finding of almost universal liver damage at necropsy.

There is thus evidence that from early childhood a high proportion of Africans have damaged livers. This has

many profound effects, but in particular it has been shown that when the liver is damaged, as in cirrhosis, it is unable to inactivate oestrogens (Glass, Edmondson, and Soll, 1940). Nor is cirrhosis necessary, for Hibbs (1947) and Klatskin, Salter, and Humm (1947) have described gynaecomastia in malnutrition. It has been shown that the liver fails to inactivate oestrogens where there is vitamin B deficiency (Biskind and Biskind, 1942) or where there is a lack of lipotropic factors (György, 1945). Lipotropic factor deficiency gives rise to fatty infiltration of the liver similar to that found in kwashiorkor (Davies, 1948a, b, c). Therefore, if Africans have damaged livers, which generally is known to be the case, then signs of oestrinization should be widespread in Africa.

Evidence of Oestrinization in Africans

If from an early age Africans are subjected to oestrinization many profound changes might be expected. Most of the experiments performed to show the effect of oestrogens have been carried out in mice and other laboratory animals, and it is as yet uncertain how far similar changes occur in humans. The general change in males is to produce "feminization" associated with certain mental changes. Feminization will be manifested by changes in the general body configuration and by gynaecomastia. The endocrine glands are affected and the incidence of certain endocrine disorders should be altered. The known carcinogenic properties of oestrogens might be expected to be shown by a high incidence of certain types of cancer, and since, if this theory is correct, oestrinization occurs from an early age, then the age incidence of these cancers would probably be lower than in Europeans. In African females a high incidence of cystic hyperplasia of the breast, of endometriosis, and of endometrial cancer might be expected. All these possibilities will be briefly examined.

Changes in the Body Configuration of Africans.—Lewis (1942) points out that the anthropologists have long sought to explain the origin of racial characteristics by the action of hormones and have so explained the slender build of the Bantu (castration effect). Gordon (1933), dealing with amentia in the East African, stated: "I may mention that I have found gynaecomastia to be common and also a marked general feminoid tendency in the males of our own tribes." He also mentioned the frequency of bilateral hyperplasia of the parotids, a condition now known to be associated with malnutrition in Africans (Davies, 1948a; Gillman, Gilbert, and Gillman, 1947). It may be mentioned in passing that the work of Gordon and of Vint (1933) on the African brain and mentality, which attracted great interest, would appear to have been carried out on Africans showing what we now recognize as severe stigmata of malnutrition possibly associated with endocrine upset. In association with this feminization it may be noted that the body and beard hair of Africans is often very soft and downy and they rarely shave, while in health their skins are beautifully soft and satiny.

Gynaecomastia—This is uncommon in temperate regions. Karsner (1946) gives its incidence in the U.S. Army as 16 per 100,000 and in the U.S. Navy as from 6.96 to 9.46 per 100,000. There is no doubt about its frequency in Africans: Gelfand (1948) comments on its prevalence in Rhodesia, and in a recent survey of 500 railway workers in Nairobi Trowell (1948) found it present in moderate degree in 3% of these and in severe degree in 2%. Thus 5% of these supposedly healthy men exhibited this lesion, which Karsner (1946) concluded to be an indication of oestrogen upset in the male. My colleague Mr. E. M. K. Muwazi informs me that in certain parts of Uganda operations for the removal of these unsightly male breasts are often demanded, and in Mulago Hospital this is an operation not infrequently performed. Testicular atrophy is often associated with gynaecomastia, and while no figures can be given there is no doubt that testicular atrophy and oligospermia are common in Africans.

Inguinal Hernia.—Dr. Burrows has kindly drawn my attention to the effects of oestrogens in causing inguinal hernia to develop in mice. While no figures of exact incidence can be given there is no doubt that hernia is very common in Africans. Connell (1930) has mentioned its frequency in African males and also its relative infrequency in African women. Herniae are extremely common in Uganda and a vast number are operated upon each year. Undescended testicle does not appear to be common, but I am informed (McAdam, 1949—personal communication) that at operation the cord is often found to be short.

Thyrotoxicosis.—The rarity of thyrotoxicosis in Africans is a striking feature of African medicine. While goitre is not uncommon, and is even remarkably common in certain endemic foci—e.g., in Sierra Leone (Blacklock, 1925)—thyrotoxicosis is very rare (Gelfand, 1948). Of the many thousands of biopsy specimens examined in Kampala between 1931 and 1949 only two specimens were found to come from Africans diagnosed as having thyrotoxicosis and with the history supporting this diagnosis. In the same period only one case came to necropsy. Thyroid adenomata, however, are common. Oestrogens are reported as having an inhibitory action on the thyroid (Cameron, 1945), and, though this not so great as to be effective in moderate or severe thyrotoxicosis, in mild cases they may be effective (Farbman, 1944). While the cause of the rarity of thyrotoxicosis in Africans is obscure, it is possible that oestrinization might account for its rarity.

Effects in the Female.—Cystic hyperplasia in women is now attributed to excessive oestrogen stimulation (Willis, 1948). Ellis (1937) refers to the frequency of this condition in African women, finding that in the women he examined 51% had nodules of cystic hyperplasia and 14% had cysts. He thought that, since he found carcinoma of the breast to be unusual in African women, cystic hyperplasia could not be a precancerous lesion. Evidence of the effects of excessive oestrogen stimulation upon the endometrium appears, in my experience, to be frequently seen in the biopsies submitted, but as these are from selected cases no figures can be given. Evidence of infertility is also difficult to produce, but the abortion rate is believed to be high. In their studies in Ulanga, Tanganyika Territory, the Culwicks (1938) found that the fertility rate of the older women was very low, possibly correlated with a severe famine in their youth, but that the fertility rate of the young women, while low, was much higher than that of the older women.

Cancer in Africans

The influence of oestrogens in the causation of cancer has aroused very great interest. The study of the incidence of cancer in Africans is beset with immense difficulties. There is an almost total lack of reliable vital statistics in Central Africa; women come to hospital less often than men, and the severe bed-pressure means that where nothing further can be done patients have to be returned to their homes, while adequate diagnostic facilities are concentrated in a few centres only.

An important consideration is that relatively few Africans live to enter the cancer age, for, as Barnard and Robb-Smith (1945) point out, almost half the total cancer mortality in England and Wales occurs in persons of 65 years and

over. Statements about the ages of Africans must be accepted with great caution, but it has been shown (Davies, 1948c) that the average age at death of persons coming to necropsy at Mulago Hospital is just over 28 years, and that of 2,162 patients only 21 definitely were above the age of 60 years and 1,635 were below the age of 40 years. Considering this, there would appear to be no shortage of cancer in Africans.

In the absence of proper statistics it is possible to put forward for consideration only the figures obtained from the necropsy records of Mulago Hospital over the period 1931–49 and the figures of the cancers diagnosed from biopsy specimens in the Kampala Laboratory over the same period. This laboratory serves the whole of Uganda, with a population of about five millions. All Asiatic and European cases have been excluded, and, so far as possible, all cases which subsequently came to necropsy at Mulago Hospital; and, while it is not possible to say that all such have been excluded, it is certain that the overlap is slight. Endless discussion could take place over the exact ascription of many of these tumours, so the diagnosis recorded in each case has been accepted as the correct one. Cases of metastatic cancer in which the primary source was not stated are not included in Table I.

TABLE I.—*Cancers in Uganda Africans*

Site	Biopsy	Necropsy	Site	Biopsy	Necropsy
Carcinoma					
Skin:			Gall-bladder	0	2
Epithelioma	152	2	Ureter	1	0

	Biopsy	Necropsy	Total
Carcinoma	690	101	791
Sarcoma	158	12	170
Reticulo-endothelial tumours	181	36	217
Special tumours	114	17	131
Total	1,143	166	1,309

A number of interesting features are displayed in this table, but comments will be made only on points bearing on the hypothesis under discussion. The details can be compared with those of other published series of cancers in Africans: Smith and Elmes (1934, Nigeria), Ledentu (1934, Cameroons), Vint (1935, Kenya), and Elmes and Baldwin (1947, Nigeria).

Carcinoma of the Male Breast

A high incidence of carcinoma of the male breast has been recorded by several observers. Their findings are summed up in Table II and compared with the figures given by Willis (1948).

TABLE II.—*Comparative Figures of Carcinoma of the Breast*

Locality	Total Carcinoma	Total Breast Carcinoma	Male Breast Carcinoma	As % of Breast Carcinoma	As % of all Carcinoma
England and Wales, 1938	—	7,278	60	0·82	—
Victoria State, 1933–42	—	2,455	26	1·0	—
Nigeria, 1934	225	29	3	10·3	1·3
Kenya, 1935	277	25	5	20·0	1·8
Cameroons, 1934	63	11	3	27·2	4·7
Nigeria, 1947	568	84	7	8·3	1·2
Uganda, 1949	791	64	5	7·8	0·63

This table underestimates the total malignancy found in male breasts, for Vint's series contained two breast sarcomas and Elmes and Baldwin recorded two sarcomas in their cases, and in the Uganda series there were two sarcomas and one malignant endothelioma of the breast. Sarcoma of the breast is a very rare tumour, and it is possible that these cases might be anaplastic carcinomas; but the effect is still the same, as it confirms the frequency with which malignant tumours occur in the breasts of African males. To these figures may be added the statement of Gelfand (1948) that he has encountered some cases of carcinoma in the male breast.

This high incidence of male breast cancer in Africans awaits explanation, as does the high incidence of gynaecomastia. It is very difficult to incriminate such agents as parasites or trauma, and all the evidence suggests an endocrine cause.

Reticulo-endothelial Neoplasms

Oestrogens are known to have some influence over the occurrence of leukaemias and lymphosarcomas and other systemic neoplasias of the reticulo-endothelial system in mice (Furth, 1946; Greenstein, 1947). Such neoplasms figure prominently in this series, but it is difficult to estimate their exact incidence in other reports from Africa. Elmes and Baldwin do not mention leukaemia or Hodgkin's disease, but found 53 lymphosarcomas in their 1,000 cases. The generalized glandular tuberculosis seen in Africans can mimic the lesions of Hodgkin's disease, and many recorded cases may really be tuberculosis (Davies, 1947).

Many of the endotheliomas arose from lymph glands, and these tumours were the subject of a special study by Hennessey (1942). Vint recorded 15 endotheliomas from Kenya (2.7% of his tumours). But in view of the strictures passed by Willis (1948) upon this diagnosis it is difficult to assess the true status of these tumours. In spite of this, however, reticulo-endothelial neoplasms are common in Africans and usually occur in young persons. Thus of nine necropsy cases of lymphosarcoma the average age was 23.9 years, the oldest being a man of 42: of six cases of reticulum-cell sarcoma the average age was 38.9 years, the oldest being a man of 50; and of five leukaemias all were young adults with an average age of 25.9 years.

Willis (1948) states that while lymphosarcoma is not rare in youth it is predominantly a disease of middle and old age (the mean age of his cases was 52 years). Gelfand (1948) states that leukaemia in the African, whether myelogenous or lymphatic, runs an acute or subacute course.

While the youth of these subjects may be only a reflection of the short life of Africans, these tumours appear predominantly in young males and run an acute course. Another common tumour of Africans which Willis puts in this class of tumours is Kaposi sarcoma, which has a peculiar sex incidence. Elmes and Baldwin record its incidence as 2.4 : 1 in their cases. It is possible that some cases of this disease are masquerading in this series under other names endothelioma or fibrosarcoma.

Primary Liver Carcinoma

This is a very common tumour in Africa, and so far no satisfactory explanation of its frequency has been adduced, but it has been suggested elsewhere that this might also be induced by oestrinization (Davies, 1948b). It has an almost constant association with a slowly developing Laennec type cirrhosis, and Schenken and Burns (1943) have caused hepatomas to develop in mice by oestrogen administration. In Africans it is predominantly a disease of young adult males, the age incidence in this series of 20 necropsy cases being an average of 36.6 years. From such cancerous livers carcinogenic substances have been isolated, probably sterols, as they have from non-cancerous African livers but not from the livers of Europeans or American negroes. Failure of oestrogen inactivation would account for the finding of carcinogens in both cancerous and non-cancerous Bantu livers.

Uterine Carcinoma; Testicular Tumours

Uterine Carcinoma.—Considering the greater ease of diagnosis of cervical cancer as compared with endometrial cancer, the incidence of the latter in Uganda would appear to be relatively high. Willis quotes various authorities who suggest that the proportion of cervical to body cancer is about three or four to one.

Testicular Tumours.—These would appear to be rare in Uganda and in Nigeria, and no interstitial-cell tumours are recorded.

Discussion

The evidence which suggests that oestrinization is widespread in Africa and accounts for many of its peculiar pathological conditions requires to be supported by studies of the sex hormone excretion of Africans. To judge by what is known to be true of cirrhotic cases (Lloyd and Williams, 1948), these should present evidence of sex hormone upset. I know of no place in Central Africa where such studies are being carried out, but it would seem that if they were done they might produce extremely interesting results.

If the importance of oestrinization in Africans can be proved it will clearly be a matter of great value in the development of Africa. It is not to be supposed that the evil effects of oestrinization or other hormonal defects induced by malnutrition are confined to the conditions briefly discussed here. Oestrin produces changes in personality and mentality which may be of the greatest importance in African life. While only African pathology has been discussed, the known high incidence of primary hepatic carcinoma in other parts of the world, such as Java and Malaya, may mean that this hypothesis is applicable to conditions there. It is realized that much written here is mere speculative opinion and that other alternative explanations are possible to cover these differences between African and temperate pathology. But all I wish is to lay this hypothesis before those interested in tropical medicine and suggest that the possibility of sex hormone upset in malnourished Africans is a subject worthy of further study.

Summary

It is suggested that the different incidence of a number of pathological states in Africans from that found in Europe can be explained upon the hypothesis that, owing to widespread malnutrition and consequent liver damage, Africans are subject to wholesale oestrinization.

This hypothesis arose out of an investigation into malnutrition carried out in conjunction with Dr. H. C. Trowell and Dr. E. G. Holmes. I am grateful to them, to Dr. A. B. Raper, and to others of my colleagues for help and advice, and also to Dr. H. Burrows. The paper is published with permission of the D.M.S., Uganda.

On the island of Tinian in the trust territory of the Pacific administered by the United States Navy nearly 100 lepers are receiving medical treatment that will enable many of them to return to their former homes and occupations. Work at the leper colony is part of a health service the United States Navy is performing in the Marianas, Caroline, and Marshall Islands. The Navy, acting for the United States Government, directs civil administration in the former Japanese-mandated islands under a trusteeship agreement with the United Nations. A first step in the medical programme was the gathering of information on the health and incidence of disease among the 50,000 natives of the islands. As the 100 inhabited trust islands are scattered over a wide area the U.S.S. *Whidbey*, a small cargo ship fitted as a medical centre, is headquarters for the staff making the survey. The *Whidbey* started making the rounds in the Marshall area in August, 1948. It stops at each inhabited island long enough for a physical and dental examination of every inhabitant. The ship's medical staff consists of two doctors, one dentist, one medical service corps officer, and 10 hospital ratings. One of the most important functions of the staff is to discover cases of leprosy. Although emergency treatment is given on the vessel when necessary, other ships collect the lepers and take them to Tinian Island.

DIRECT VEIN GRAFT IN RUPTURE OF POPLITEAL ARTERY

REPORT OF A CASE

BY

PETER MARTIN, M.Chir., F.R.C.S.Ed.

Surgeon, Chelmsford Hospital Group and Tilbury Hospital Group

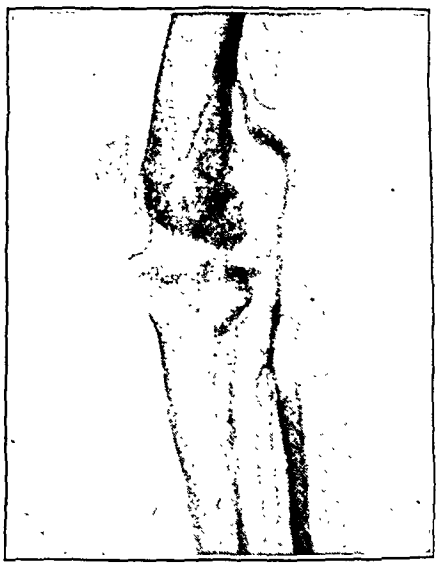
(From the Department of Vascular Surgery, Postgraduate Medical School of London, Hammersmith)

Since the advent of anticoagulants, especially heparin, it has been advised many times in textbooks and in discussions that where there is a gap in the course of a main vessel resulting from trauma, or possibly from the excision of an aneurysm or other operative procedure, and where direct suture is impracticable, reconstitution should be effected by vein-grafting. There are, however, very few such cases reported in the literature in which grafting has been successful. In a subject with healthy arteries it is probably safe to say that the main vessel can be interrupted with impunity, provided that there is not such extensive damage to the soft parts that the collateral vessels themselves are divided and precluded from carrying out their function. Where such damage exists, and where there is other reason to suppose that sufficient collaterals will not function properly, the restoration of blood flow can be secured by means of a vein graft with or without the use of a vitallium tube.

The following case in which a direct vein graft without a tube was used to bridge a gap in the popliteal artery is of interest. The immediate result was successful, but other circumstances led to an amputation six months later.

Case Report

On July 1, 1947, a farm labourer aged 19 was driving a tractor and backing towards an upturned harrow when he fell backwards off the driving-seat on to the spikes of the harrow. He sustained a lateral perforating wound of the left knee, the harrow point passing across the popliteal surface of the femur and grazing it. The wound of entry was considerably lacerated and there was much damage and bruising of the subcutaneous and deep tissues in this area. At the time of examination some two hours later the foot was cold and pulseless and there was a sock anaesthesia. His general condition was good.



Operation was performed with a pneumatic tourniquet *in situ*. The wounds were explored and devitalized tissue was excised. Through an additional posterior midline incision the contents of the popliteal fossa were examined. The popliteal artery was extensively bruised and in spasm over a distance of 2 in. (5 cm.) and the media in one segment was partially divided. The posterior tibial nerve was intact, but the lateral popliteal nerve showed considerable bruising. The affected segment of the popliteal artery was excised and extensive subintimal haemorrhages were found in this part.

As there was much damage to the collaterals, the result of the original trauma, it was felt to be essential to restore the blood flow in the main vessel, and as no vitallium-flanged tubes were available a piece of the internal saphenous vein was excised from the opposite thigh and sutured to the patent cut ends of the popliteal artery. Suture was effected at each end by eight interrupted sutures of silk on the finest needle. The tourniquet was released and, although the graft bulged somewhat, pulsation was immediately apparent, extending into the distal segment of the popliteal artery, and there was no leakage. The wound, owing to its dirty and soiled condition, was lightly packed with petroleum jelly gauze.

A pronounced reactive hyperaemia was immediately apparent in the foot, and both the dorsalis pedis and posterior tibial pulses were full and easily palpable (blood pressure 200/130). The patient was given heparin, but in spite of the fact that the clotting-time was never above eight minutes severe haemorrhage recurred on the following day and re-exploration and a transfusion were necessary. A tributary of the popliteal vein was found to be bleeding and was tied. The graft was pulsating satisfactorily. Heparin was stopped.

The next day haemorrhage occurred again, and this time was seen to be coming from the popliteal surface of the damaged femur. The graft was still pulsating well and there was no undue bulging; a further transfusion was given. Convalescence proceeded satisfactorily, but from the time of the accident anaesthesia was present over the distribution of the lateral popliteal nerve, and there was similarly a motor paralysis of the lateral and anterior tibial muscles.

On August 25—i.e., almost eight weeks after the injury—an arteriogram (see illustration) showed slight stricture at the site of the anastomosis, but the blood flow was satisfactory and the blood supply of the foot was completely adequate, although the pulses of the affected leg were not quite so good as those in the contralateral limb. Unfortunately a flexion contracture of the knee-joint started and, in spite of treatment, became more pronounced. On January 8, 1948—i.e., six months after the injury—the popliteal area was again explored and was found to be a mass of extremely dense fibrous tissue; in the process of dissecting this out the popliteal artery was irreparably damaged and gangrene of the toes occurred, necessitating amputation of the leg below the knee at the site of election on March 16.

Arteriogram taken eight weeks after injury.

Comment

Experimentally, Murray (1940) has shown that direct vein-grafting of a gap in an artery is completely successful provided the animal is given heparin for about 72 hours, the bleeding-time being maintained at 12 to 20 minutes. He examined the grafts after a four-weeks interval, when patency and hypertrophy of the graft were seen, the latter being confirmed microscopically—in fact, it appeared that the vein had become like an artery.

Certain points of interest arise from my case: (1) The graft was working satisfactorily and was in fact not easy to distinguish from normal popliteal artery when directly inspected 48 hours after the transplantation. (2) The blood pressure following operation was up to 200/130 for some time, and the graft did not bulge significantly. (3) Owing to excessive haemorrhage following operation heparin was not used for more than 24 hours, nor was the clotting-time increased above eight minutes, yet the graft remained patent. I do not suggest that heparin is inadvisable or unnecessary in such cases. (4) Should flanged vitallium tubes not be available, or should they not be considered advisable, it seems that a direct vein graft to bridge the gap in an artery is a rational procedure and has a good chance of success.

THE AGGLUTININ ANTI-M ASSOCIATED WITH PREGNANCY

REPORT ON TWO CASES

BY

C. CHRISTOPHER BOWLEY, M.B., M.R.C.O.G.

Obstetric and Gynaecological Registrar, North Middlesex Hospital

AND

I. DUNSFORD

National Blood Transfusion Service, Sheffield

In the following two cases of pregnancy the agglutinin anti-M was detected.

Case 1

Mrs. A, aged 27, was expecting delivery of her first child on December 22, 1946. The serological findings are shown in the Table.

May 20.—Mrs. A : Group A Rh-negative (cde/cde). W.R. negative. No abnormal antibodies active at 37° C.

August 1.—Mr. A : Group O Rh-positive. His cells were not agglutinated at 37° C. by his wife's serum (saved from May 20 and stored at −20° C.).

December 3.—Mrs. A : Serum contains an antibody active at 37° C. agglutinating 13 different red cell suspensions (two Rh-negative and 11 Rh-positive), each known to contain the antigen M, but did not agglutinate seven different red cell suspensions all lacking in the antigen M.

December 10.—Mrs. A : Red cells—Group A Rh-negative N.P. Serum—action of antibody identical with that of a known anti-M when tested against 100 unknown cells. Titre of antibody 128 at 37° C., 20° C., and 4° C., with a weak reaction at 37° C. and a visual reaction at 4° C.

December 16.—Mrs. A was delivered of an apparently healthy child showing no clinical signs of haemolytic disease of the newborn. The placenta was normal in appearance and weight. *Baby A* (cord blood) : Apparently Group A Rh-negative ; M,N,P. The direct Coombs test was negative. The child's cells were strongly agglutinated at 37° C. by its mother's serum. Haemoglobin at 24 hours was 162% Haldane. *Mrs. A* : Findings as before. The titre against the same M-positive cell 64 at 37° C. (weak reaction), 64 at 20° C., and 128 at 4° C. (visual reaction). *Mr. A* : Group O Rh-positive (cDe/cde) ; M,N. His cells were strongly agglutinated at 37° C. by his wife's serum.

December 23.—Mother and child were discharged from hospital. The child was fully breast-fed and clinically normal.

Table Showing the Serological Findings in Family A

Date	Mrs. A	Mr. A	Baby A
20/5/46	Group A Rh-negative (cde/cde). No abnormal antibodies at 37° C.	—	—
1/8/46	—	Group O Rh-positive. Cells not agglutinated by wife's serum	—
3/12/46	Antibody present active at 37° C.	—	—
10/12/46	Group A Rh-negative; N,P. Antibody identical with anti-M against 100 unknown cells. Titre: 1: 128 at 37° C. (weak reaction); 1: 128 at 20° C.; 1 : 128 at 4° C. (visual reaction)	—	—
16/12/46	Titre: 1: 64 at 37° C. (weak reaction); 1: 64 at 20° C.; 1: 128 at 4° C. (visual reaction)	Group O Rh-positive (cDe/cde); M,N. Cells agglutinated at 37° C. by his wife's serum	Group A Rh-negative ; M,N,P. Coombs's test negative. Cells agglutinated at 37° C. by maternal serum
5/4/47	Titre: 1:8 at 37° C.	—	Group A Rh-negative ; M,N,P

April 5, 1947.—Baby A : Aged 3½ months. Examined by paediatrician and judged to be normal in all respects. Blood typed as Group A Rh-negative ; M,N,P. Mrs. A : Anti-M still active at 37° C. with a titre of 8.

Case 2

Mrs. B, a 3-gravida, was admitted to the puerperal sepsis ward on March 13, 1947, three days after delivery, requiring transfusion. Blood was sent for Rhesus typing and cross-matching.

March 14.—Group O Rh-negative (cde/cde); N. No abnormal antibodies were demonstrable at 37° C., but at 20° C. and 4° C. an antibody was present, behaving as an anti-M with a titre of 2. Cross-matching was carried out at 37° C. and 4° C., and Group O Rh-negative N blood was transfused satisfactorily.

March 26.—Infant B : Aged 15 days. Clinically normal, having shown no signs of haemolytic disease of the newborn since birth. Blood Group O Rh-positive (CDe/cde); M,N. The direct Coombs test was negative. The child's cells were strongly agglutinated by its mother's serum at 20° C. but not at 37° C. Mr. B : Group A Rh-positive (CDe cde); M. His cells were strongly agglutinated by his wife's serum at 20° C. but not at 37° C.

Discussion

The findings of an abnormal antibody in maternal sera during pregnancy may generally be taken as indicating iso-immunization, with the future possibility of haemolytic disease of the newborn. It is our contention that the detection of anti-M in maternal serum during the course of pregnancy or the puerperium should not be considered as having the same significance as the detection of such abnormal antibodies as the Rhesus iso-agglutinins. In fact, anti-M, like anti-P (Dunsford, 1949), is to be considered as a naturally occurring antibody, comparable with anti-A or anti-B, but of rarer occurrence.

The literature contains few references to the iso-agglutinin anti-M. Wiener and Forer (1941) and Wiener (1942) have reported what appears to be immune anti-M in two cases following incompatible transfusion, but such an occurrence is so rare and anti-M so weak an antigen in man that M and N factors are ignored in normal transfusion work. Anti-M in association with pregnancy has been reported in only two cases (Paterson *et al.*, 1942 ; McFarlane, 1945), while we have knowledge of three more recently discovered cases. De Kromme and Van Der Spek (1948) have reported a case in which it was suggested that anti-N was associated with haemolytic disease of the newborn, but it was not investigated fully nor was the association proved.

In the cases of Paterson *et al.* and McFarlane and in our Case 2 anti-M was present as a typical cold agglutinin active at 20° C. and 4° C. In no case was there evidence of haemolytic disease of the newborn. Following these three cases, that of our Case 1 is of additional value in that the antibody was strongly active at body temperature with a titre of 128, but again there was no evidence of haemolytic disease of the newborn.

It is believed that Rh is a stronger antigen in man than M (McFarlane, 1945), and if anti-M and anti-Rh are produced by a similar process—namely, iso-immunization—it would be reasonable to suppose that Group N, Rh-negative multigravidae who have borne M or MN Rh-positive children, and have produced anti-M, should also have produced anti-Rh. McFarlane's case and our Case 2 both fall into this category, but in neither case was anti-Rh detected. This suggests that the anti-M present was a natural and not an immune antibody. It will be appreciated that a case reported by Wiener and Forer (1941) in

which both anti-M and anti-Rh were produced by an incompatible transfusion, and another discovered by Stratton (personal communication), with both antibodies present in pregnancy, do not negative this hypothesis.

Secondly, clinical and serological manifestations of haemolytic disease of the newborn were entirely absent in the case of Mrs. A, in whom the antibody was known to have increased in titre during the pregnancy and to have become active against the cells of the foetus and its father at body temperature. Similar findings with an immune iso-agglutinin are almost invariably followed by affection of the newborn.

Finally, a technique of differentiating immune and naturally occurring antibodies was applied to these sera. This technique, described by Boorman and Dodd (1947), is the comparison of the titre of the agglutinin in saline with the titre of the agglutinin when human serum, lacking the antigen to the antibody under examination, is used as diluent in place of saline. Boorman and Dodd found enhancement of titre in serum in which immune antibodies were present, whereas naturally occurring antibodies showed no enhancement. In the cases of Mrs. A and Mrs. B there was no evidence of titre enhancement, further confirming the theory that these anti-M agglutinins were of natural occurrence.

Reason must be given why in the case of Mrs. A the titre of the antibody rose during the intrauterine life of the foetus if the antibody was of natural occurrence. This phenomenon has been reported by Jonsson (1936) and others in the case of naturally occurring anti-A and anti-B, and not infrequently observed by one of us (I.D.). Similar observations have been made in Rh-negative women who, having produced Rh antibodies in previous pregnancies, reproduce these antibodies in increasing titre in a subsequent pregnancy, even though carrying a normal Rh-negative foetus. This can be explained by the supposition that there has been a non-specific stimulation of already existing antibodies during the course of pregnancy.

In the case of Mrs. A an explanation of the alteration of the antibody activity so that agglutination of the infant's and of the father's cells occurred at 37° C. is found in the work of Kettel (1930), who proved that the thermal amplitude of a cold agglutinin—e.g., anti-M—is directly proportional to its titre. The titre of 1 : 128 of Mrs. A's anti-M is the first reported to have reached sufficient strength to react at body temperature.

Tovey (1944) has suggested that anti-M or anti-N agglutinins will appear only rarely in the serum of a mother who is carrying a baby of dissimilar M or N type. This he suggests is due to the pronounced non-specific absorptive capacity of human tissues for these iso-agglutinins. This may explain why Mrs. A's anti-M, though active at 37° C., did not cause haemolytic disease of the newborn.

Summary

Two cases in which the agglutinin anti-M was associated with pregnancy are reported, and the literature on the subject is reviewed.

Reasons are suggested for considering these anti-M agglutinins to be naturally occurring antibodies.

The relation of anti-M to the aetiology of haemolytic disease of the newborn is discussed.

We wish to thank Mr. J. E. Stacey and Mr. L. B. Patrick for permission to quote their cases whilst one of us (C.C.B.) was at the Jessop Hospital for Women, Sheffield; also Dr. E. F. Aubert (late regional transfusion officer) and his successor, Lieutenant-Colonel R. H. Malone, for their valuable advice and permission to publish this note. Dr. A. E. Mourant, of the Ministry of Health Blood Group Reference Laboratory, was kind enough to confirm the findings of Mrs. A's serum.

Note.—An anti-M with the same thermal amplitude as Mrs. A's has been reported to us by Dr. Tovey, of the Regional Blood Transfusion Laboratory, Bristol, and one of us (I.D.) has recently found another anti-M associated with pregnancy, in which case the child, though M-positive, was clinically normal.

THE RHESUS FACTOR D^U

A NOTE ON ITS PRACTICAL IMPORTANCE

BY

F. STRATTON, M.D., D.P.H.

Regional Transfusion Officer, Manchester; Special Lecturer in Human Serology, University of Manchester

AND

P. H. RENTON, M.D., B.Sc.

Deputy Regional Transfusion Officer, Manchester

Rh testing is being undertaken in many laboratories either as a test in antenatal cases or for selecting Rh-negative blood donors. Fisher has suggested that the reactions of the various Rh types should be explained in terms of three pairs of allelic genes, C-c, D-d, and E-e, controlling the presence of the corresponding antigens.

Additional alleles, C^w and D^u, have been detected at the C-c and D-d loci, and it is with D^u at the D-d locus that this paper deals. This theory is fully explained by Mollison, Mourant, and Race (1948).

The D antigen is the most important of the Rh antigens, and a person is now referred to as being "D-positive" or "D-negative" according to whether his erythrocytes do or do not possess the D antigen. In the Manchester area there are about 18% of D-negative and about 82% of D-positive persons, so that, if the rarer subgroups are excluded from our consideration for the moment, it will be seen that this classification roughly corresponds to "Rh-positive" and "Rh-negative."

The D^u Group

When blood cells were being typed for Rh it was noticed that some anti-Rh (anti-D) testing sera reacted with certain blood samples positively, whereas others, apparently equally good testing sera, failed to react with these cell samples. Further examination of these cells revealed that they reacted with up to 45% of anti-D sera only; these cell samples may of course also react positively, or negatively, with anti-C and anti-E sera in the usual way. This special type of D antigen was tentatively called D^u (Stratton, 1946); subsequently cells of types CDu/cde, cDu/cde, and cDuE/cde were discovered and recognized (Race, Sanger, and Lawler, 1948a, 1949b; Stratton and Renton, 1948).

It was later found that some types of D^u cell were so weak in their reactions that they would give saline agglutination with no anti-D typing sera, or in some cases with only a very few. Nevertheless, it was found that these cells would

give a positive Coombs reaction when tested with certain strong incomplete anti-D sera, but they failed to give a positive albumin reaction in the same circumstances.

It should not be imagined that the difference between Du and D is one of strength of reaction only; we have conclusively shown that there is a qualitative difference between D and Du and between one Du blood and another. Moreover, we were able to show that Du is an inherited allele or modification of D.

It will be observed that the anti-D sera which react with Du are really anti-D + Du sera, whereas those which fail to react with Du are anti-D sera alone. The term Du therefore defines a series of alleles or modifications of the main antigen D at the D-d locus which differ qualitatively and quantitatively from D, and in many cases from each other. The reactions of Du may therefore be summarized as follows:

1. They react with anything from 0–45% of anti-D sera (anti-D + Du) by saline agglutination; those that react with none are referred to as "low-grade" type Du and those that react with many as "high-grade."

2. They all give positive Coombs reactions when examined with certain strong incomplete anti-D sera.

3. With the exception of a few of the high-grade Dus, they all fail to give positive albumin reactions with incomplete anti-D sera.

Thus the reactions of Du-positive cells vary from those scarcely distinguishable from D right down to those detectable only by the Coombs test, using special incomplete anti-D sera. These reactions are shown in the Table.

Table Showing Percentage of Anti-D Sera Giving Positive Results (the Actual Percentage of Positive Results Depends on the Individual Cell Sample Tested)

Test	Antigen in Cells			
	D	High-grade Du	Low-grade Du	d
Agglutination in albumin* ..	60–90%	0–10%	Nil	Nil
Agglutination in saline† ..	60–100%	5–45%	Nil	Nil
Coombs's reaction*	90–100%	70–100%	20–60%	Nil

* The sera tested were the strongest available. † The sera tested were a random selection.

It was found by examining large numbers of cell samples that about half the cells apparently of genotype Cde/cde are in reality CDue/cde and about one in nine of those apparently cdE/cde are really cDuE/cde. The proportions are probably greater than this, since our study was made especially into low-grade forms of Du-containing cells.

Practical Importance

When testing blood samples for Rh the nature and extent of the test depend upon the reason for its performance. If the test is being done in the case of antenatal patients or other persons to determine whether or not they can be immunized to Rh, then it is necessary to determine only whether the person is D-positive or D-negative.

On the other hand, when testing a person's cells to ascertain whether he is Rh-negative for the purpose of being a blood donor, one must make sure that the donor is not only D-negative but C-negative and E-negative as well. This is because the recipient's serum may contain not only anti-D but anti-C and, rarely, anti-E antibodies as well.

We have examined several blood samples from mothers of genotypes Cde/cde and cdE/cde whose sera contained anti-D antibodies. Careful examination failed to show the presence of Du in any of these cell samples, and consequently, so far as we have ascertained at the present time, the presence of Du indicates that the cell sample is D-positive. Therefore, in the first instance mentioned above, when testing antenatal patients, anti-D + Du sera may be used and a Du person considered to be D-positive.

A child suffering from hypoplastic anaemia has been treated by Professor Gaisford with multiple blood transfusions from the age of 10 months; he is now 6 years of age, and during this period he has been transfused approximately six times yearly and has received about 100 pints (57 litres) of D-positive blood. Recently he was found to be of group CDue/cde, but no abnormal antibodies have been detected in his serum. In addition, he has more recently received a few pints of Rh-negative blood until the nature of the Du group was more fully understood, but it seems that this child has failed to respond to the D antigen.

That a child of this age can respond to antigenic stimuli is shown by another case. A boy suffering from a similar condition was seen by one of us (F.S.) when about 8 years of age. He was Rh-negative and had strong Rh antibodies in his serum. He had likewise been treated over a period of about three years with multiple transfusions.

Van Loghem (1947, 1948) showed that Du may become antigenic to D-negative persons, since immunization of an Rh-negative volunteer with blood of CDue/cde resulted in the formation of incomplete anti-D antibodies; whilst in Mollison's case (personal communication) a CDue/cde baby suffered from haemolytic disease of the newborn caused by incomplete anti-D antibodies in the maternal serum.

In the second instance, therefore, in which we are selecting Rh-negative donors for transfusion purposes, it is necessary to exclude the Du-containing groups. The most practical way to avoid these is by using anti-C and anti-E sera in addition to anti-D when typing the blood. This will not only eliminate D-positive blood but also Cde/cde and cdE/cde as well as CDue/cde and cDuE/cde—that is to say, the vast majority of Du-positive blood. In certain populations—for example, negro—where the incidence of cDe/cde may be as high as 45%, this will not suffice, and it will be necessary to do a Coombs test, using incomplete anti-D sera to exclude group cDue/cde, which has a very low frequency in England (probably about 0.015%).

Furthermore, Du is of practical importance when it is proposed to use Cde/cde and cdE/cde cells for determinating the presence of anti-C and/or anti-E agglutinins respectively in Rh antisera. If these cells are used but in reality contain the Du group and are CDue/cde and cDuE/cde, the Rh antisera will falsely be thought to contain anti-C or anti-E, whereas the reaction may be due to the presence of anti-D reacting with the Du component of the cells. This is of very great importance if the sera are to be used subsequently as test sera, and considerable confusion will result.

In the cross-matching test it is as well to remember that, should one encounter a donor whose cells contain Du and a recipient's serum containing incomplete anti-D antibodies, the albumin test, often recommended for cross-matching, will be negative but the Coombs test will reveal the incompatibility. In general, when investigating sera for atypical antibodies both the Coombs and the albumin tests should be used, in case the antibody be of a type which reacts in only one of these tests. For our own part we are led to believe that the Coombs test is the one to be preferred in the detection of antibodies where only a single test can be performed.

Conclusion

In conclusion it should be emphasized that only a proportion of anti-Rh agglutinating sera react well with Du-positive cells, and, since Du bloods differ from one another

and from D qualitatively as well as quantitatively, sera giving the strongest agglutination with Du cells are not always those with the highest titres when tested against D-positive cells. In carrying out an examination of Du cells, using incomplete anti-D sera and the Coombs test or albumin test, the sera have also to be specially selected for this purpose.

The observations made in this paper apply, in the main, to the differentiation of Du from d. The determination of Du cells and their isolation and differentiation from the D-containing erythrocytes, on the other hand, is a difficult and complicated matter. The differing reactions of Du blood and the difficulties of knowing precisely what antibodies anti-Rh sera contain add to these difficulties.

To overcome this it is necessary to examine large numbers of cells of all types containing both the D antigen and the Du antigen combined with C and/or E, as well as cells containing the C and E antigens alone (i.e., types Cde/cde and cdE/cde); each type should be examined with very many varieties of anti-Rh agglutinating sera and incomplete antisera. The results should be tabulated and compared one with another, and any new cell should be put through this process and its reactions compared with those of other cells; by this means it is possible to give the type of the new cell which has been tested. In making our comprehensive table, for example, we used 49 Rh-agglutinating sera and 12 incomplete Rh antisera.

Full theoretical and explanatory results are not given in this short paper, but a further publication will show these and the manner in which they have been worked out.

New regulations have been introduced by the Government to improve the standard of purity of milk. The Minister of Agriculture and Fisheries becomes responsible for the registration of dairy farmers and farms, the inspection of cattle on dairy farms, and the enforcement of the regulations on dairy farms (unless they relate to diseases communicable to man). If the Minister proposes to refuse or cancel a registration, provision is made for objections to be referred to a tribunal and for representations to be made to the Minister. Local authorities are still responsible for the provisions which apply to milk distributors other than dairy farmers and for the registration of these milk distributors and of dairies. Local authorities also continue to be responsible for the provisions relating to diseases communicable to man. The present powers relating to infected milk are extended to enable a medical officer of health to stop the sale of milk, or to require milk to be diverted for heat treatment, if there is evidence that it is infected with organisms of disease communicable to man. A medical officer of health may also require milk to be diverted for heat treatment if he has reasonable grounds for suspecting that it is so infected. There are a number of minor changes in the regulations relating to buildings, the cleansing of vessels and utensils, and the distribution of milk and its protection against contamination. In particular, provision is made for modern practices in dairying, including the use of mechanical refrigeration for cooling and approved chemical agents for the cleansing of appliances. A Central Advisory Committee and County Advisory Committee will be set up to review and make recommendations on the operation and administration of the regulations.

NOTES ON AN EXPERIMENTAL STUDY OF INTELLECTUAL DETERIORATION

BY

SIDNEY CROWN, M.A.

Research Fellow, Department of Psychology, Institute of Psychiatry, Maudsley Hospital, London

The term "intellectual deterioration" means for the clinician a decline in intelligence as a result of a brain lesion, chronic mental illness, or old age. The psychologist has been satisfied to define intellectual deterioration operationally in terms of the tests he uses to measure it. These tests have been designed on the assumption made originally by Babcock (1930) that vocabulary level is a valid index of the pre-morbid intelligence of the patient. By a comparison of the score on a vocabulary test with the score on a pure test of intelligence an assessment of the degree of deterioration is made.

Hunt (1944), however, has questioned the assumption that vocabulary level is a valid index of pre-morbid ability. He points out that vocabulary may suffer as a consequence of the disorder; also that for unintelligent subjects vocabulary may be an imperfect indicator of ability.

The theory underlying the design of tests of intellectual deterioration can be verified only by a large-scale study of individuals suffering from a disorder known to cause intellectual deterioration which responds to clinical treatment. The present investigation was performed as a preliminary to the design of a large-scale investigation, and the results seemed of sufficient interest to report.

The Investigation

The subjects tested were three women and one man suffering from myxoedema. This disease seemed suitable for the investigation, as it causes apparent intellectual deterioration and responds rapidly to treatment by thyroxine. The main disadvantage from the point of view of research is its rarity. In the course of over a year only four subjects were found at the endocrine clinic of a large hospital. These were tested before starting treatment and three months later, when by clinical criteria they had recovered.

Tests Used

1. *Raven's Progressive Matrices Test.*—This is a non-verbal intelligence test. The untimed version was given.

2. *The Mill Hill Vocabulary Scale.*—This is a 32-item vocabulary test of the synonyms type. The scores on both these tests were converted into intelligence quotients (S.D. 16 points) by means of a table constructed in this department. An index of deterioration is obtained from these two tests by the formula:

$$\frac{\text{Matrices I.Q.}}{\text{Vocabulary I.Q.}} \times 100,$$

A quotient below 90 implies a certain degree of intellectual deterioration.

3. *The Shipley* (1940) *Test.*—There are two subtests: (*a*) A 20-item "abstractions" intelligence test consisting of a series of problems graded in difficulty in which the subject fills in a missing letter or figure. The first of these is: 1, 2, 3, 4, 5, – and the reasoning becomes more complex as the test progresses. There is a ten-minute time limit and the score is expressed as an abstractions mental age. (*b*) The second part of the Shipley test is a 40-item vocabulary test of the synonyms type, with a ten-minute time limit, from which a vocabulary mental age is obtained. From a comparison of the abstractions and vocabulary raw scores Shipley gives an index of deterioration (called by him a conceptual quotient) which is designed on virtually the same principle as the matrices/Mill Hill vocabulary

index. He considers any C.Q. over 90 as probably normal, under 70 as pathological, with various gradations between these.

The scores on the matrices and abstractions tests were not corrected for the natural decline of intelligence with age, as we were interested not in an individual patient's score on the tests but rather in the changes in the scores on the tests after treatment.

Results

The test/re-test results are given in the accompanying Table. The most obvious result is that the intelligence level of the group tends to rise. On the matrices test the

Table Showing Test Results

Case	Sex	Age		Matrices	Mill Hill Vocab.	D.I.	Abstr. Mental Age (months)	Vocab. Mental Age (months)	D.I.
1	F	60	Test	72	94	77	—	181	—
			Re-test	94	100	94	—	194	—
2	F	27	Test	69	97	67	125	189	66
			Re-test	84	111	76	125	208	60
3	F	46	Test	80	100	80	177	189	93
			Re-test	98	100	98	207	198	104
4	M	45	Test	79	106	74	162	204	88
			Re-test	102	106	96	166	204	89

D.I. = Deterioration Index.

Statistical significance of the differences between test/re-test scores:

Matrices	Students t	= 13·67;	P = <0·01
Mill Hill vocabulary	"	= 1·51;	P = 0·23
Shipley abstractions	"	= 1·20;	P = 0·35
Shipley vocabulary	"	= 2·57;	P = 0·08

gain is of 22, 18, 18, and 24 points, giving a mean gain of 20.5 I.Q. points. The results on the abstractions test are equivocal, partly because one paper was spoiled. One subject's score rises by 2½ years of abstraction age and one by four months; the other remains unchanged.

However, the most important result from both the theoretical and the practical points of view is that the vocabulary scores also show a tendency to rise (though less markedly). Thus the Mill Hill vocabulary I.Q. rises in two out of four cases by 6 points and 14 points, which gives a mean gain of 5 vocabulary I.Q. points for the whole group. The Shipley vocabulary mental age rises in three cases by 13, 19, and 9 months—a mean gain on the whole group of 10.2 months of vocabulary mental age. This finding would seem to undermine the assumption that vocabulary level is unaffected by pathological processes in the brain and that it is a valid index of the pre-morbid intelligence of intellectually deteriorated patients. The variability of the vocabulary scores also raises interesting problems regarding the nature of the aphasic disorder suffered by patients who are intellectually deteriorated.

The assessment of intellectual deterioration is a practical problem in the psychiatric clinic. The results provide evidence on the use of indices of deterioration to express the differential decline in abilities. As patients recover clinically these indices should rise, thus approaching the normal. This is so for all indices derived from the matrices and Mill Hill vocabulary tests. But of the three indices of deterioration derived from the Shipley tests one actually falls, thus showing the patient to be more deteriorated after treatment, despite the fact that her intelligence level has risen by 18 points of I.Q. on the matrices test. The other Shipley indices of deterioration rise after treatment, but neither before nor after treatment do they indicate any degree of deterioration, although this is clearly shown in the indices derived from the matrices and Mill Hill vocabulary tests. Further, statistical tests of significance show that, whereas the changes in the scores on the abstractions test are insignificant, those on the Shipley vocabulary test approach the 5% level. The evidence would seem to speak against the use of the Shipley test for the estimation of intellectual deterioration, and would suggest that an index of deterioration derived from the matrices and Mill Hill vocabulary tests is more valid. Further, no provision is made by Shipley for correcting scores on the abstractions test for the natural decline in intelligence with age. This is essential in estimating the extent of intellectual deterioration for any individual case. It may be done for the matrices test from data provided by Foulds and Raven (1948).

The criticism may be levelled against our findings that the increase in the intelligence and vocabulary scores could arise simply as a result of the practice effect of repeating the tests. Statistical tests of significance show, however, that the changes in scores on the matrices test are significant at the 1% level, and that the changes in scores on the Shipley vocabulary test approach the 5% level. Although the changes in scores on the Mill Hill vocabulary test are not statistically significant at the usually accepted levels, it must be noted that this vocabulary test is untimed, which would tend to diminish the possibility of practice effect. Also the alternative version of the test, given additionally to the first patient, showed a similar rise in vocabulary. It therefore seems unlikely that the changes after treatment in the intelligence and vocabulary scores are entirely the result of practice.

Summary and Conclusions

The intelligence level of three patients suffering from myxoedema was raised greatly after treatment by thyroxine.

Scores on two vocabulary tests also rose, but by a smaller amount.

The results provide some empirical evidence contrary to the general assumption that vocabulary level is unaffected in cases of intellectual deterioration.

Until a more accurate method is available a comparison of scores on the matrices and Mill Hill vocabulary tests is recommended for the estimation of intellectual deterioration.

I would like to thank Dr. P. M. F. Bishop, Guy's Hospital, for allowing me to test patients under his care.

Note.—I would be grateful if any physician in charge of patients suffering from myxoedema who is interested in having them psychologically tested would inform me at the Institute of Psychiatry, Maudsley Hospital, London, S.E.5.

The place of clinical pathology in medicine and the status of its practitioners have lately been engaging the attention of the health authorities of Cuba. As a result of negotiations between the Sociedad Cubana de Medicos Laboratoristas Clinicos and the Cuban Health Authorities the following principles have been accepted by the National Council of Public Health of Cuba and approved by the Cuban Minister of Public Health, Dr. Carlos M. Ramirez Corria: (1) It is acknowledged that clinical pathology is exclusively a branch of the medical profession, and as such it should be subject to the laws that govern the practice of medicine in general. (2) The director of any clinical laboratory should be a fully recognized medical practitioner. (3) It is to be understood that the clinical laboratory is where the physician specializes in this specific branch of medicine by practising clinical analysis and following scientific laws, with the purpose of guiding the practitioner in diagnosis, prognosis, and treatment. (4) The clinical pathologist should keep secret the results of his work, with the exception of those which are specified by law.

Medical Memoranda

Tuberculous Meningitis with Paraplegia as the Dominant Feature

The following case is put on record as it presented certain unusual features which caused difficulty in arriving at a correct diagnosis.

CASE REPORT

A Gurkha recruit aged 16 was admitted to hospital on May 14, 1948, with a small septic laceration of the left knee. This healed without obvious complication, but on May 18 he developed a sudden rise of temperature. This was provisionally diagnosed as a malarial attack, which was treated by routine methods. However, as no malaria parasites were seen in blood-slides and his pyrexia did not subside with antimalarial measures, it was considered that he might have developed a secondary generalized infection from the primary focus on the left knee. Penicillin and sulphathiazole were therefore given, but without clinical improvement.

On May 23 he had to be catheterized, and patches of anaesthesia were found distributed over the lower chest and flanks. During the next 24 hours he developed a rapidly progressive paraplegia and became drowsy. Lumbar puncture performed at this time revealed diminished C.S.F. pressure, a raised protein content, and 9 cells per c.mm. A blood count showed 27,000 white cells (90% polymorphs).

I was invited at this stage to see the case in company with Lieutenant G. Watts, R.A.M.C., and found the patient practically comatose. There was some stiffness of the neck, the pupils were dilated and fixed, and he had a complete flaccid paraplegia with loss of all reflexes, including the abdominal reflexes. The level of loss of sensation was difficult to determine accurately owing to his inability to co-operate, but he reacted to pin-prick above approximately the fourth dorsal level. There was no clear line of demarcation of sensory loss. The spine showed no obvious abnormality.

A cisternal puncture revealed a pressure of 200 mm. of water. The C.S.F. was clear and there were only 4 cells per c.mm. Tubercle bacilli were not found. A tentative diagnosis of spinal compression following an epidural abscess was made. It was surmised that the septic laceration of the knee had been the portal of entry for organisms causing a generalized infection.

The patient died on May 25. Owing to religious objection a post-mortem examination limited to the spine and skull only was permitted.

Pathology.—On exposing the theca no epidural abscess was found. The dura was much thickened, and on being incised the subdural space was seen to be filled with thick gelatinous and fibrinous pus. The dura was covered with shaggy exudate and studded with tubercles. A similar appearance was observed on the surface of the cord. These changes were most pronounced between the levels of D 10 and D 4, and had apparently produced a complete spinal block. The base of the brain presented similar but very much less marked appearances, and the lining of the ventricles was studded with small tubercles.

Histological examination showed that the cord itself was largely unaffected, but the pia and arachnoid were grossly thickened and contained large numbers of lymphocytes, histiocytes, polymorphs, and giant cells. Bacteriological culture gave a growth of human tubercle bacilli.

COMMENT

A case of tuberculous meningitis with pronounced early spinal symptoms is described. This form of the disease seems to be comparatively rare, and in this instance it ran a very rapid course, there being only seven days between the onset of the pyrexial stage and death. The sudden fever and the presence of a focus of sepsis on the knee suggested a pyogenic cause for the spinal signs, and the true diagnosis was revealed only at necropsy.

Four cases with a similar chain of features occurring in Singapore between 1938 and 1942 were described by Ransome and Montiero (1947). Though there are certain differences between their cases and the one described here, the march of events was the same—pyrexia, paraplegia, meningeal signs, and death. In their cases the onset and course of the condition were more gradual, the illness lasting about three weeks. In describing the nervous signs they noted the patchy sensory loss and the difficulty in demarcating the limit of sensation, but stated that the muscular paresis of the legs never became complete. However, in the main essentials the case here described corresponds with the clinical and pathological picture as observed by Ransome and Montiero.

I am indebted to Captain J. C. Gould, R.A.M.C., for his report on the pathological findings.

Case of Oesophageal Carcinoma

This is, I believe, the first recorded case of carcinoma of the oesophagus in a patient suffering from anorexia nervosa.

CASE REPORT

The patient was an unmarried woman aged 38. During a pleasure cruise in the Thames Estuary 21 years ago she became much alarmed when a large wave broke over her. She began to "tremble and go stiff all over," she lost her voice; all inclination for food left her, and she had a "breakdown." She had to give up her job. Anorexia persisted thereafter, and she said that she had lived on 2 pints (1.1 litres) of milk and two cups of sweet tea each day until her admission. Her weight, which was 5 st. 1 lb. (31.75 kg.), tended to confirm the truth of this statement. Eighteen years ago amenorrhoea and daily vomiting began and persisted for a year; there was no further change until three months before admission, when retrosternal oppression occurred during meals, and rapid loss of weight began. A month before admission vomiting started, and for the last few days had been almost continuous.

On examination she was a sallow, emaciated virgo intacta, with no stigmata of hypovitaminosis. Slight proteinuria and a few small, easily felt hard lymph nodes in the left posterior triangle were the only positive physical signs. A provisional diagnosis of anorexia nervosa was made, but the recent alteration in symptoms suggested oesophageal obstruction, and a barium swallow was carried out; this revealed a tight stricture in the lower third of the oesophagus, which was subsequently shown by oesophagoscopy and biopsy to be due to the presence of a squamous-celled carcinoma.

Radiotherapy was begun, and gastrostomy was performed. The liver was rapidly invaded, however, and become enormously enlarged and irregular. After the appearance of ascites and oedema of the legs, downhill progress was rapid, and four months after admission the patient died.

At necropsy an ulcerating growth of the oesophagus involving the whole wall from the bifurcation of the trachea to the cardia was found. The liver weighed 4,150 g. and was packed with carcinomatous masses. There were two enlarged lymph nodes containing secondary deposits at the bifurcation of the aorta, and one in the left side of the neck. Microscopically, many branches of the portal vein in the liver were shown to contain plugs of growth.

COMMENT

The feature of interest in this case is the relation of the long-standing psychological disturbance to the development of oesophageal cancer. Lawrence Abel (1929) states that two-thirds of his cases of carcinoma of the oesophagus were preceded by an incident of emotional stress, and Guisez (1925) has said that half of the cases in his series had a similar history. Abel suggests that the neoplasm arises at the site of pre-existing spasm of the muscle wall, and refers to his own observations and those of Guisez that mental stress is often a cause of oesophageal spasm.

If the patient's symptoms before the development of carcinoma had been due to oesophageal spasm, it is reasonable to suppose that during the twenty-years history some of the oesophageal dilatation and hypertrophy characteristically the result of spasm ought to have developed. This was not so, and one is forced to the conclusion that in this patient, at any rate, whatever aetiological relation there may have been between mental stress and oesophageal cancer, spasm played no part.

Dr. E. R. Cullinan, under whose care this patient was admitted, has kindly given permission for the publication of this report.

Localized Fat Atrophy After Jelly-fish Sting

The following case is worth recording because of its unique nature.

CASE REPORT

A V.A.D. nursing member aged 27 was bathing in the sea at Trincomalee, Ceylon, at about 10 p.m. on February 26, 1948. As she was climbing up the steps to come out of the water the anterior part of the left thigh and the left leg just above the ankle came in contact with the tentacles of a jelly-fish, which for the moment became wrapped round the limb. A severe stinging sensation was at once felt, followed almost immediately by large urticarial weals on the sites of contact. She returned home and went to bed, though the pain continued throughout the night and was severe enough to interfere with sleep. There was never any collapse, dyspnoea, respiratory embarrassment, or generalized urticaria, and she reported sick at the hospital the next morning.

When seen about 12 hours after the accident she was still complaining of an exceptional amount of pain, and urticarial weals with vesiculation were present across the anterior aspect of the middle third of the thigh and the leg for about 4 in. (10 cm.) above the ankle. There were no general symptoms beyond slight malaise. The patient was rested in bed and calamine lotion applied; the urticaria subsided in a week, leaving a purplish red discoloration of the skin, which persisted, though gradually fading, for about six months. Some oedema of the left foot and ankle appeared on the second and third days and lasted for some three weeks.

The discoloured skin of the affected areas remained remarkably sensitive, and even three months later a stinging sensation could be appreciated on contact with water.

On May 9 the patient again reported, stating that for the past three weeks she had noticed her left leg becoming thinner. The cutaneous discoloration was still just apparent; there appeared to be a complete disappearance of the subcutaneous fat in these areas, the left thigh being 1¾ in. (4.4 cm.) thinner at 6½ in. (16.5 cm.) above the patella, and the left leg ¾ in. (1.9 cm.) thinner at 2 in. (5 cm.) above the ankle. There was no loss of power, no muscular wasting, and no reflex or sensory changes. A radiograph of the lower limb showed no abnormality. No treatment was given and the patient was again seen on November 21. A certain amount of redeposition of fat had taken place in the intervening six months—the left thigh now showing 1¼ in. (3.16 cm.) of wasting and the left leg about ½ in. (1.25 cm.)—and the tendency seemed to be towards a slow return to normal. The accompanying photograph, which was taken on November 22, shows the degree of fat atrophy then present.

COMMENT

Jelly-fish of various types are very prevalent round the coast of Ceylon during the months of February and March, and a number were known to be about at the time: it is regretted, however, that the exact species responsible was not identified.

Jelly-fish stings are capable of causing a variety of local and general symptoms, mostly suggestive of excess histamine liberation. Urticaria in varying degrees of severity is the most usual local reaction, and may be followed by a profuse weeping eczema (Allen, 1920: quoted by Joslin *et al.*, 1940). General symptoms include shock, cardiac distress, and dyspnoea, but these were entirely lacking in this case. The degree of skin discoloration and the length of its persistence were both exceptional, though it is not very uncommon for some reddening of the skin to be present at the end of three months.

Lipodystrophy, or atrophy of the subcutaneous fat, is well recognized in diabetic patients treated with insulin, and is especially frequent in children and to a less extent in women, but is scarcely ever seen in adult males (Joslin *et al.*, 1940). This observation may have some bearing on the present case: it has been suggested that the androgen may protect the adult male and lack of it may account for the frequency in women and children, for hypogonadal adult males may occasionally suffer from insulin lipodystrophy (Walderstrom: quoted by Joslin *et al*, 1940). I have been unable to trace any similar case in the literature.

My thanks are due to the Medical Director-General of the Navy for permission to publish this case.

A new type of rubber surgical glove has been developed in the U.S.A. to relieve cases of dermatitis caused by the continual wearing of rubber gloves, which is a problem chiefly faced by surgeons, who may have to cease working for considerable periods to obtain relief. A rubber company of Akron, Ohio, has announced that it is now producing this special glove, and a number of doctors have reported that they are effective.—B.U.P.

Reviews

ADVANCES IN RADIOLOGY

Modern Trends in Diagnostic Radiology. By J. W. McLaren, M.A., M.R.C.S., L.R.C.P., D.M.R.E. (Pp. 464; 381 illustrations. £3.) London: Butterworth. 1948.

Dr. J. W. McLaren took on a difficult task when he accepted the editorship of this work, and its signal success says much for his judgment in selecting a team of distinguished writers, choosing the subjects for them to write about, and, most important of all, excluding what is already established or beyond the limit of future probability. He has cast his net wide for both subjects and authors, and sets the standard himself in an early chapter on radiology in research. This section emphasizes the research work of A. E. Barclay, whose recent death was lamented by the whole world of radiology.

In a brief review it is not possible to do justice to the articles in this book—all of them good, and some superlatively so. It is therefore courteous to mention the work of some of Dr. McLaren's distinguished colleagues from abroad. The article by Baclesse on tumours of the pharynx and larynx is of first importance, and adds much to our knowledge. Waldenstrom on pulmonary haemosiderosis, Nordentoft on colonic disease in children, Steinert on renal tuberculosis, and Edling on urethrocystography, all maintain the high standards of Scandinavia. Later in the book comes an excellent article by the late Eric Lysholm on ventriculography and associated subjects. Of equal merit is a contribution on cerebral angiography by Engeset and Kristiansen, of Oslo.

Of the British contributors, Meiklejohn has made a noteworthy contribution on occupational pulmonary diseases, and L. G. Blair and Whateley Davidson have written most readably on the lung. Of particular interest is Holmes Sellors's account of post-operative chest complications. Peter Kerley has written a brilliant and typically provocative description of sarcoidosis. Blair Hartley knows a great deal about foetal abnormalities, and writes with authority about all sorts of monstrosities. Eric Samuel gives an excellent account of modern gastro-intestinal work. James Brailsford discusses abnormalities of the spine, a subject of which he has made a lifelong study.

The book ends with two unusual articles of great worth. Sir Lionel Whitby's chapter on blood changes is brilliant, and should be read by all who have charge of *x*-ray departments, and W. A. Levitt's account of the law relating to radiology is a model of lucidity.

This book is a pleasure to read and a credit to the editor and his colleagues. It is pleasant to think that it has been so well received as to demand an early second edition, now well on the way.

S. COCHRANE SHANKS.

VARICOSE VEINS

Les Varices et leurs Associations Pathologiques. By Louis Gerson. Second edition. Preface by Professor L. Justin-Besançon. (Pp. 260; 57 figures. 850 francs.) Paris: G. Doin. 1948.

This book on varicose veins and their pathological associations is an enlarged and revised edition of a volume which appeared in 1934. The physiology of the venous system and the aetiology of varicosities are considered briefly, and there are accounts of the clinical types of varicose veins and their complications, and of methods of treatment.

Many of the clinical descriptions are good, particularly those discussing the aetiology of the different types of ulceration, the skin changes, and other complications. English readers will, however, find much to criticize in the over-elaboration of pathological interpretation, the tendency to theoretical generalizations, and the narrow attitude towards treatment. The author considers that local congenital defects are the most important aetiological factors—thus accounting for varicosities in unusual situations. There are many who will disagree with the view that the main internal saphenous vein invariably dilates from the top, and also with the statement that oedema is frequently present in uncomplicated varicose veins. There is a full account of the author's technique of injection and the possible complications. The solutions specially favoured are sodium salicylate, iodine in sodium iodide, sodium morrhuate, and quinine urethane. There is no attempt to link injection treatment with direct surgical attack, and all operative treatment is in fact ignored.

The various types of phlebitis receive scant notice in relation to their frequency and importance. Phlegmasia alba dolens is considered in some detail, but the author's interpretation of this subject will appeal to few. His conception is that phlegmasia is an allergic phenomenon developed in an individual who has had septicaemia and been sensitized to the streptococcus. It is on this assumption that all the local complications of ulceration are interpreted. The illustrations are good, but references to the literature are scanty and consist of a few French papers only.

REGINALD PAYNE.

BIOLOGICAL ASSAY

Principles of Biological Assay. By C. W. Emmens, D.Sc., Ph.D. With foreword by Sir Percival Hartley, C.B.E., *M.C.*, D.Sc., F.R.S. (Pp. 206. £1 1s.) London: Chapman and Hall. 1948.

The gratitude of all responsible for conducting biological assays is undoubtedly due to Dr. Emmens and his publishers. There is no other book in the English language that covers exactly the same ground as this. It explains in detail and with great patience how modern methods of factorial design and statistical analysis may be applied to the planning and execution of biological assay as well as to estimating potency and to evaluating the error of the estimate. The subject is discussed from the fitting of curves to the analysis of co-variance. Both types of biological response are considered—those expressible as a continuous variate and those of the quantal type, with the application of probits to them.

Although the book is not easy reading, and is presumably not intended for casual dipping or even continuous perusal, few who practise biological assay will fail to find in it answers to some of the problems already encountered. All will gain valuable suggestions for improving, and often for simultaneously simplifying, current procedures.

Yet there remains a faint sense of dissatisfaction with this book, not only due to the fact that the title is misleading—for it describes far less the principles than the practice of applied statistical methods. A book still needs to be written that will consider, from the standpoint of the chemist and biologist, with due regard to statistical concepts, the methodological and even ethical problems that continuously confront the bio-assayists. One of these problems is the subject of a specific injunction by Dr. Emmens (p. 69), when he writes, "If we design a test so that a particular set of degrees of freedom is allotted for error, only this set should be used whether or not other sources of variation prove to be significant in the particular test analysed." But there are many other questions to which he does not refer or only does so in passing. What, for example, is his opinion of the almost universal practice among pharmacologists and others of "adjusting" dosage so that it is proportional to the body-weight of the test animal? If this weight does not affect response, why adjust? If it does, is not a full analysis of co-variance needed to establish the simple linear relationship that alone could justify the practice in question?

A few errors have been detected in the text of this book, and it is unfortunate that Dr. Emmens writes of "test material" (p. 6) and "test objects" (p. 56) in referring to the animals or tissues used for biological assay, for the former expression, at any rate, is taken by most assayists to mean the sample to be assayed. On the other hand, at least one reader is gratified to find Dr. Emmens writing of a "four-point assay" without reference or other comment, in spite of the fact that the expression was introduced as recently as 1942 (*Biochemical Journal*, 36, 407), with quotation marks. The phrase seems to have passed into current usage without any kind of official sanction. This leaves open the awkward question whether a "six-point" assay means two by three or three by two: it has

been used in both senses. The useful term "metameter," suggested by Hogben and first introduced with due acknowledgment in the same paper as "four-point assay," apparently does not appeal to Dr. Emmens. He has devoted little space to discussing the choice of metameter, often one of the most difficult of all the decisions the bio-assayist has to take. And there is much more to say than he does about litter-mate control.

The production and arrangement of the book are admirable. Because of the large number of diagrams and tables, including those for χ^2 (p. 142) and corrected probits (p. 142), the price of the book must be adjudged entirely reasonable.

A. L. BACHARACH.

TRAUMATIC SURGERY

An Atlas of Traumatic Surgery. By Josep Trueta, M.D. Barcelona, Hon.D.Sc., Hon.F.R.C.S Canada. (Pp. 150; 188 figures. £1 10s.) Oxford: Blackwell Scientific Publications. 1949.

Except for a brief introduction this book consists entirely of the clinical notes of patients suffering from serious injuries of the limbs—injuries for which many surgeons would have regarded immediate amputation as imperative a short time ago. That the limbs have been restored to useful function is a tribute to the methods advocated (and largely introduced) by Professor Trueta. He has wisely placed this record before surgeons with little comment, for the evidence he produces is overwhelming. Only those who in the two great wars have had to struggle with similar cases can really appreciate his superb achievements. When they remember that he began his work under the terrible conditions of the Spanish war they must equally admire his courage.

Although most of the cases described occurred under the conditions of war the methods adopted have a full application in those grave injuries which happen in peace and appear to be inseparable from mechanical progress. By these means many limbs may be conserved, but it must not be imagined that they are to be saved by petroleum jelly gauze and plaster. Professor Trueta makes his technique look so simple that one is apt to forget the skill and infinite attention to detail that lie behind it. Only by similar attention can these results be reproduced. The book presents a record of which Professor Trueta may well be proud and for which many surgeons engaged in the treatment of injuries must be grateful.

HENRY SOUTTAR.

PATHOLOGY FOR SURGEONS

Surgical Pathology. By Peter A. Herbut, M.D. (Pp. 710; 410 illustrations. £3.) London: Henry Kimpton. 1949.

The diagnosis and successful treatment of many surgical diseases depend on the naked-eye recognition during operation of the pathological lesions they produce. In other words, the successful surgeon must, within the limits of his own field, become a highly skilled morbid anatomist. His training in this "pathology of the living" depends to a large degree on close collaboration with a skilled morbid histologist. The more "pathologically minded" the surgeon and the more "surgically minded" the histologist, the more successful, especially from the patients' viewpoint, will the partnership become. The body of scientific knowledge built up in this way is what surgeons really mean by "surgical pathology."

There is clear evidence throughout this book that the author, a pathologist, has worked in the closest collaboration with a team of keen surgeons. The bulk of the text is made up of clear and concise descriptions of the naked-eye and histological features of all the more common (and a considerable number of the rarer) surgical lesions. These are illustrated by many clear and well-chosen photomicrographs.

The book is arranged according to anatomical regions, and the author has in mind the needs of the otorhinolaryngologist, the urologist, and the gynaecologist as well as the general surgeon. There are no introductory chapters on general pathology or bacteriology, as in several other books which carry the same title, but each chapter opens with a short account of the anatomy and embryology of the region under discussion. For this reason the book would be of little value to the undergraduate before he had completed a full course of study in general pathology. It is clearly intended for the postgraduate who has made surgery his career, and within its limitations it will certainly be of great service to him.

The book contains occasional sentences which convey the sort of information provided by a punch-card system. We are told, for instance, in the description of an infected human bite that the lesion is found most frequently in "young white male adults in the third decade of life," and in connexion with tattooing we are informed that "the incidence of syphilis among tattooed persons is less than it is among the general population of the same stratum." Progressive myositis ossificans is said to be associated with a "small big toe." The description of gangrene due to arterial ischaemia is short and should be expanded. An accurate account of gas gangrene should also be included. It is disappointing to find no detailed account of healing, and the description of the repair of a fracture is far too short. There are a number of simple spelling mistakes. These criticisms should not detract from the value to the surgeon of the large amount of accurate descriptive pathology contained in the book.

GEOFFREY HADFIELD.

CHILD ANALYSIS

Contributions to Psycho-Analysis. 1921–1945 By Melanie Klein. With an introduction by Ernest Jones. (Pp. 416. 21s.) *London: The Hogarth Press.*

Although the distinction of being the first child-analyst in this country belongs to Mary Chadwick, a pupil of Sachs who employed the principles of Freud and Hug-Hellmuth in the psycho-analysis of children, there is no doubt that progress in this field in Britain was guided at first by Melanie Klein, and subsequently controlled by Anna Freud. Mrs. Klein invented the "play-technique" of association, and during the early phase of her work made valuable contributions to our knowledge of "pre-genital" phases of infancy and childhood, a period which till then had been only scantily observed. Indeed had Klein been content to consolidate this earlier work on the "oral-sadistic" phase, on forerunners of the super-ego, and on the animistic reactions of the small child, her scientific reputation would stand much higher than it now does.

Unfortunately, in her later phase Mrs. Klein undertook the thankless task of reconstructing hypothetically the mental development of infants from birth to the age of two and a half (when they are first capable of direct analysis). Influenced mainly by psychiatric concepts, she began to postulate certain nodal "positions" during the first year, labelling these respectively "paranoid," "depressive," and "manic" positions. To these postulates she added the theory that the Oedipus phase is already activated by oro-phallic sadistic impulses in the second quarter of the first year; and that already at this period an effective super-ego organization exists. These views were adumbrated in her papers on mourning and manic-depression, and caused profound divergences of opinion in the British Psycho-analytical Society.

All but the last three papers in the present volume belong to her earlier phase. Although of unequal merit, they are worth reading not only for their clinical content but for their picture of pre-genital development. The last paper, on the Oedipus complex, was written after a two-year wrangle in the society, and presents the issues in a very minor key. One would not gather from it that her theories on the dynamic influence of sadistic fantasy, on narcissism, and on "internal objects" are opposed in many fundamental respects to the theories of Freud. There is, in fact, a very remarkable resemblance between the Kleinian concept of fantasy and the Jungian archetype of the collective unconscious; also between her evaluation of psychic traumata and that of Rank.

The depth of the cleavage can be gathered from the fact that Ernest Jones, usually an acute and objective critic of psycho-analytical developments, has contributed a laudatory introduction which does not err on the side of impartiality.

EDWARD GLOVER.

MEMORIES OF A LONG LIFE

Mostly Memories. By William Guy, LL.D.(Penn.), F.R.C.S., F.R.S.Ed. (Pp. 360; illustrated. 15s.) Edinburgh: C. J. Cousland and Sons. 1949.

Dr. Guy will be 90 in December of this year, and like most people who reach an advanced age he lives largely in his memories. These are on the whole happy ones and well worth recording.

He is a "truant" doctor, a Norwich general practitioner's son who had his medical education at Edinburgh. This he followed with seven years of general practice in Cumberland before he took to dentistry—the specialty in which he eventually reached the top of his profession. He took his F.R.C.S.Ed. from the Edinburgh Dental School, where he was later part-time dean for 34 years.

What most impresses one in reading this book is the versatility of the man. Not content with the conduct of a successful practice and his task of reforming the school, he took an active part in the affairs of the British Dental Association. He became an outstanding figure in the association, filling almost every responsible position in it, and thereby helping to make dental history.

Dr. Guy gives a detailed account of the various campaigns in which he was engaged—usually successfully. His influence can be traced in the legislation which prescribed the registration of dentists; in the establishment of the Dental Board; and in the formation of the Army Dental Corps. He served on the General Medical Council as one of the first of the dental representatives. Here he tells us he established a reputation for being "pig-headed," of which he is not ashamed, for he says he never had any liking for the line of least resistance. He was active in the proceedings of the International Dental Federation, and has much to say about his attendance at its annual meetings. This bare recital of a selection from his interests will suffice to show that he was, as he says, "a very busy man," but it by no means covers his extraordinary range of activities. In Edinburgh social life he was for many years a prominent figure, in great request as an after-dinner speaker with a gift for expression in topical verse. Of this he gives us many examples, frequently in parody, often in the vernacular. Those members of our Association who were present at the Edinburgh meeting in 1927 may remember him as the chairman of a smoking concert given to the representatives, at which he enabled us to realize why he was such a popular local celebrity.

This book should be welcome in various quarters. Edinburgh people, resident or exiled, will like his affection for the city of his adoption. Dentists who take pride in the progress of their profession should be glad to read about the man who did so much for it in so many ways. And anybody who likes to read about well-known people will find many stories of eminent actors and artists whom he met or entertained. Dr. Guy is to be congratulated on his long, useful, and happy life, and on his wonderful memory.

ALFRED COX.

It is heartening to see once more upon a title-page the name of Crile, and to know that the son of a distinguished father has already proved his worth. *Practical Aspects of Thyroid Disease*, by George Crile, junior (pp. 355; 101 figures; £1 10s.; Philadelphia and London: W. B. Saunders Company; 1949), is a readable and useful book in which the author has for the most part drawn upon his own experience of a thousand cases of diseased thyroid. Though an expert surgeon, he affords due prominence to the recent advances in non-operative treatment and gives the indications for medical and surgical therapy with just discrimination. The most interesting sections for most readers will probably be those on the treatment of hyperthyroidism by propylthiouracil and radioactive iodine. To quote one passage: "At the present time the mortality and morbidity following treatment of hyperthyroidism with propylthiouracil over a period of one year are probably lower than that of thyroidectomy in the hands of skilful surgeons and are much lower than that of thyroidectomy in the hands of the surgeon who occasionally performs a thyroidectomy." This, from a surgeon, should induce both surgeons and physicians to look into this book. It is of handy size, well printed, and freely illustrated. The chapters on technique contain little that is new, but the section on cancer of the thyroid is of special interest.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY SEPTEMBER 24 1949

CHILD HEALTH PLANNING

A recent Chadwick lecture entitled "A Health Service for Children," by Dr. Helen Mackay, was briefly reported in the *Journal* (April 30, p. 768), but now that it has been published as a pamphlet[1] it is possible to consider her conclusions in the light of developments already envisaged or actually achieved under the Health Act or in other ways. Deficiencies in existing provisions, according to Dr. Mackay, were in three categories. First was the lack of training of the general practitioner in paediatrics, and hence the great pressure on the hospitals for services which might often be much better provided in the home. No doubt the new proposals of the General Medical Council will in time help to remedy this, and medical-school deans might well study carefully the suggestions made by Professor W. S. Craig and his colleagues[2] in this *Journal* for showing students how mothers and children can be helped by a family doctor in the course of a general practice.

Next Dr. Mackay comments on the lack of close association between doctors working in the preventive services and those working in hospitals or in practice. "In many areas the position appears to have deteriorated since July 5 last," she states. This is a serious matter, and it is pertinent to inquire how far local health authorities have taken the advice on the integration of their services with those of the hospital boards which was given by the Ministry of Health in a circular letter[3] sent out in 1947. This suggested, in effect, the encouragement of more specialization in maternity and child-welfare work and splitting of the duties, so that so far as child health is concerned medical officers experienced in child welfare should, in the words of the circular, "gradually be allocated to the authority's child-welfare centres, and spend part of their time participating in the work of an appropriate paediatric department in a children's hospital." Unfortunately the operative word appears to be "gradually," for in the period since the time of the circular, now nearly two years, there has been little, if any, indication that authorities were doing more than filling vacancies by medical officers expected to attend antenatal clinics and welfare centres as before. The third main deficiency in Dr. Mackay's opinion is lack of trained staff in the hospital services. "At present," she states, "only a minority of hospitals dealing with children have any medical staff trained in paediatrics." It is to be hoped that such a situation will not be allowed to continue because of the need for economy. No ultimate saving to the nation will ensue if the medical care of children is "second rate," and the same applies to nursing care. The Nurses Bill threatened, or so it appeared to many, to end the training of nurses in the special care of the child, but a Government amendment suggests that some sort of reprieve has been granted. To replace a nurse with three years' training and experience in a children's hospital by a nurse with adult training and a short postgraduate course in children's nursing would be a retrograde step.

From defects Dr. Mackay passes to regional planning. For much of this she is clearly basing her views on those published by the Paediatric Committee[5] of the Royal College of Physicians, of which she was a member. But she has also had the advantage of translating the findings of the College report to an advisory committee in the North-east Metropolitan Region, where a start has been made with this and with a child health committee which includes representatives of the local health authorities. Detailed discussion of regional plans must depend very much on what is available locally, but there can be no quarrel with the proposal that in every region there should be centres "possessing the outlook and facilities of university centres, for treatment, teaching, and research." This is almost already true outside the London area, and no doubt Dr. Mackay had very much in mind the fact that London at present has only one university institute of child health.

Perhaps the most significant part of Dr. Mackay's lecture begins with the statement, "Each child will have his own general practitioner." From this is developed the idea of one member of a team at a health centre with special interest and training in paediatrics, and of a large part of the clinical work in schools and child-welfare centres being done by general practitioners interested in paediatrics. As a transition stage it is urged that forthwith "wherever there are local general practitioners who take an interest in paediatrics they should be brought into the paediatric services and their abilities used to the full." This close association at the level of everyday work between hospital paediatricians, medical officers of the health services, and general practitioners is a recurrent theme in Dr. Mackay's lecture, and could be developed at once with little cost and without waiting for buildings.

DIABETES AND GOUT

Recent observations have shed new light on the well-known relation between diabetes and gout. It will be remembered that in 1943 Shaw Dunn made the interesting discovery that alloxan, when injected into rabbits in sufficient amount, altered the blood sugar, and after 24 hours a permanent diabetic condition resulted. The observation has appeared until recently to be no more than a curious phenomenon of no physiological importance. Several workers have investigated the mechanism of the action of alloxan and have shown that substances containing sulphydryl (–SH) groups are concerned. When alloxan was injected it was found to cause a rapid decrease in the amount of glutathione in the blood,[1] and Lazarow[2] made the complementary observation that when glutathione or cysteine was injected beforehand alloxan failed to cause diabetes. Evidence has been obtained that the protective action of cysteine is due to the reduction of alloxan to its close relation dialuric acid.[3] The latest developments, indeed, hinge on dialuric acid, for it occupies a position midway between uric acid and alloxan. In 1909 Ascoli and Izar[4] showed that dog's liver contained an enzyme which converts uric acid to dialuric acid, so that probably uric acid can be converted to dialuric acid in man. There has been a difference of opinion whether this substance causes diabetes,[5] and the outcome appears to be that if there is too little glutathione in the blood dialuric acid can be oxidized to alloxan, and then diabetes occurs. Thus glutathione can protect the body against alloxan by converting it to dialuric acid, but lack of glutathione allows dialuric acid, formed from uric acid, to be turned into alloxan.

The experiment of producing diabetes in rabbits by injecting them with uric acid has actually been done by Griffiths.[6] He fed rabbits on a diet deficient in methionine and cysteine, and in the course of six weeks the glutathione was reduced to half. When one gramme of uric acid was injected into the peritoneal cavity the mean blood-sugar changes of four rabbits were very similar to those observed in four other rabbits after the injection of alloxan. There was the same initial hyperglycaemia giving place to hypoglycaemia, and the prolonged hyperglycaemia at the end of 24 hours. The injection of uric acid had no action on the blood sugar of rabbits receiving the same diet plus a supplement of methionine.

Evidence indicating a connexion between purine metabolism and diabetes has also come from another direction. Conn and his colleagues[7] at Ann Arbor have shown that in man diabetes can follow the injection of purified preparations of the adrenocorticotropic hormone of the anterior lobe of the pituitary body. There is hyperglycaemia and glycosuria, and the sugar-tolerance curves become like those of a diabetic. The excretion of uric acid in the urine is increased, and the amount of glutathione in the blood falls progressively. If an injection of glutathione is given intravenously there is a rapid fall of the blood sugar, and the urine temporarily becomes sugar-free. The authors express the view that the primary disturbance is in purine metabolism and that a substance like alloxan is produced, which in turn causes diabetes. Other observations on the effect of the adrenocorticotropic hormone have been made by Hellmann,[8] who has injected it into patients with gouty arthritis. He found it caused a rise of uric acid in the serum and an increased excretion in the urine: he also observed glycosuria. The injection of this hormone would, of course, stimulate the adrenal cortex to increase the output of its own hormones, and when the injections were discontinued the output of these hormones would cease. Three days after the injections were stopped Hellmann's patients had an acute attack of gouty arthritis, and this attack was arrested by giving adrenocorticotropin once more. We have yet to learn whether treatment of rheumatoid arthritis with compound E ("cortisone"[9]), which is a hormone of the adrenal cortex, or with adrenocorticotropin causes glycosuria.

These observations indicate a close relation between purine metabolism and blood-sugar control. The importance of this relation is emphasized by the results of metabolic studies on birds.[10-12] In the duck and the chicken the largest doses of alloxan produce no blood-sugar change. In the pigeon there is some rise of blood sugar, but the bird dies from a deposit of sodium urate over all the serous surfaces. The facts suggest that the duck is immune to alloxan because it converts it to uric acid and excretes it; the pigeon is less immune because it carries out this process less efficiently.

VIRIDANS STREPTOCOCCI IN BACTERIAL ENDOCARDITIS

The viridans streptococci—so called because on blood-containing media they produce green pigment—are the most frequent cause of subacute bacterial endocarditis, and it has been a common assumption, since Andrewes and Horder's early work, that they are derived from the mouth, where similar streptococci are found normally or associated with dental sepsis. Strong support for this

view came from Okell and Elliott,[1] who were able to culture non-haemolytic streptococci from the blood of 30 out of 40 patients immediately after dental extractions and from 12 out of 110 patients with gross oral sepsis. Further work showed that any trauma, however trivial, to septic gums or the removal of tonsils was likely to produce a temporary bacteriaemia, and that if there were diseased heart valves subacute bacterial endocarditis was a possible sequel. Among those interested in the pathogenesis of infection it is now accepted that some organisms which normally have a saprophytic existence in one part of the body may initiate infection in another part. The coliform group causing urinary infection is a good example, and the term "potential pathogen" is often applied to these bacteria. However, lessons learnt from the classification of proven pathogens, like the pneumococci, haemolytic streptococci, and staphylococci, suggested that a subdivision of these potential pathogens might yield useful information on certain points: whether, for example, a particular group within the species was most likely to be associated with infection, as happened with the Lancefield group A streptococci, and whether the strains causing infection could be more closely identified with saprophytic strains, as has proved to be the case with certain types of pneumococcus causing bronchopneumonia.

Attempts to classify bacterial species like the coliform bacilli or the viridans streptococci according to their biochemical properties have not been very successful, and the tendency lately has been to use the methods of antigenic analysis or susceptibility to specific bacteriophage for the subdivision of these families. In America attempts have already been made to classify the viridans streptococci serologically, and in this issue Professor Selbie and his colleagues report their findings in an antigenic grouping of over 200 strains of this organism from cases of subacute bacterial endocarditis and of some 50 strains each from normal throats and from dental extractions. Classification has been based on precipitation reactions with streptococcal extracts (prepared by the Fuller formamide method) against antisera to eight different strains produced in the rabbit by repeated injections of live or killed suspensions of the streptococci. By analogy with the Lancefield grouping of the haemolytic streptococci this method of antigenic analysis is likely to give only a broad grouping, dependent presumably on a carbohydrate fraction in the viridans streptococci. The authors found that most of their strains gave precipitation reactions with several antisera, and on the basis of these "pattern" reactions they have recognized three broad groups with two subgroups. Most of the endocarditis strains (181 out of 209) were distributed fairly evenly among the five groups, and all but nine of the 103 strains from teeth and throats gave positive reactions the majority of which fell into group IIa. These results indicate broadly that viridans streptococci associated with subacute bacterial endocarditis belong to the same family as the strains found in the mouth, but they do not necessarily mean that a group I streptococcus isolated from the blood is identical with a group I strain present in the throat or causing dental sepsis in the same patient; for that, more precise antigenic analysis like Griffith typing will probably be needed. It was usual to find strains falling into several groups among the streptococci isolated from the throat or from apical abscesses in individual patients, whereas strains isolated from the blood of relapsed cases of endocarditis treated by penicillin most often belonged to the same group as the original strain. These findings have been interpreted as an indication that the relapse was due to a recrudescence of the original endocardial infection and not to reinfection from the mouth, but it is doubtful if with this broad serological classification such a claim is justified, although it gains some support from the close similarity in the biochemical reactions of strains isolated from the blood of relapsed cases. No mention is made of the non-haemolytic streptococcus called by Kilian Clarke[2] *Streptococcus mutans* because of its variable morphology, and associated by him with the aetiology of dental caries. This streptococcus is a single serological type and has occasionally been found as a cause of bacterial endocarditis, which is further evidence of the close association between the organisms in the mouth and the endocardial strains, as is also the occurrence of *Haemophilus para-influenzae*, another inhabitant of the mouth, as a cause of infective endocarditis.

Penicillin therapy has profoundly altered the prognosis in this previously fatal infection, particularly if the dosage is increased to 2 million units a day for six weeks as recommended by Christie.[3] But it must be remembered that "cured" patients are often left with grossly damaged valves which usually impair cardiac efficiency and leave the patient a prey to subsequent infection. It would be interesting to know the after-histories over a five- to ten-year period of patients with infective endocarditis cured by penicillin. Much more needs to be done to prevent this infection. Rheumatic fever is the main predisposing factor, and its steadily diminishing incidence should reduce the number of young people with endocarditis; but given a patient with diseased valves—congenital defect and syphilis are the other main contributors—every effort should be made to prevent the superimposition of an infective endocarditis. Oral sepsis is a continual danger to such a patient and should be radically treated, while the

[1] *Lancet*, 1935, 2, 869.

[3] To be published shortly.

extraction of teeth, tonsillectomy, or indeed any manipulative measure that may result in a temporary bacteriaemia should be carried out only under a penicillin or sulphonamide "umbrella." This is a matter which vitally concerns the dental surgeon, who should become well acquainted with the risk of oral sepsis or of any dental operation in a patient with defective heart valves.

PENICILLIN IN EARLY SYPHILIS

Though nearly six years have passed since Mahoney and his colleagues successfully treated four seamen suffering from early syphilis with penicillin, international opinion on the optimum treatment of early syphilis is still divided. In the United States, where the records of well over half a million patients who have been treated with penicillin alone are being carefully followed and statistically investigated, adjuvant arsenicals and bismuth are held to be not only unnecessary but undesirable. In Europe, where penicillin has been available only since the end of the war, and until recently has been strictly rationed, there is a widespread unwillingness to accept it as proved on alien evidence that even in its earliest stages a grave, chronic, constitutional disease can be permanently cured by a few days' treatment. In this country, though penicillin is now accepted as an ideal treatment of attack, there is a not unnatural reluctance to abandon its well-tried predecessors. Most venereologists, with a few notable exceptions, still prefer to compromise and to consolidate their treatment with a standard course of about ten weekly injections of neoarsphenamine and bismuth, which would by itself, incidentally, cure at least 70% of early infections.

Elsewhere in this issue J. W. Eames and D. H. Miller have tried to assess the results of this combined treatment in the face of a high default rate from surveillance due to the rapid release of their patients from the Services. With statistical and actuarial aid they claim to have demonstrated a cumulative post-treatment relapse rate of 15% at 18 months in addition to a treatment failure rate (sero-resistance) of 3.9% in secondary cases and 0.9% in seropositive primary cases. That these results are appreciably worse than those reported after similar treatment by McElligott, Jefferiss, and Willcox[1] in this country and after penicillin alone by Sternberg and Leifer[2] and others in the United States is doubtless due to a laudable desire to take no chances with patients whose follow-up is likely to be jeopardized by an early return to civil life. Many will be surprised, however, to read that all patients whose blood tests were positive four months after the end of treatment were summarily classified as failures and treated again. Apparently no attempt was made to gain some idea of the serological pattern—to find out whether the titre of the test was rising, falling, or stationary. It is now well recognized that the serum reactions in treated early syphilis often take many months to revert to negative and that so long as the titre continues to decline a slow disappearance of reagin, even lasting a year or longer, is in no way suggestive of failure of treatment. Indeed in some cases of true relapse the initial serological response is often surprisingly rapid.

There is still a tendency for the clinician to place too blind a faith in blood tests and also perhaps for the serologist to believe too implicitly in his own technical modifications and in the specificity of his antigens. Until standard methods and, what is even more important, standardized reagents are employed it will still be possible for a patient to be cured in one clinic and not in another. The new cardio-lipin-lecithin antigen is becoming increasingly popular in the United States, and is said to be stable and unaffected by changes of climate or temperature. When its optimum level of sensitivity has been ascertained and its manufacture standardized and simplified the problem of the exact significance of serum reactions may perhaps be nearer solution than it is to-day.

That the toxic effects of arsenic are rarely seen in military patients is doubtless due to their age, sex, and good physical condition. A far greater toll is usual in civil clinics, where women, the undernourished, and men in the higher age groups are treated, and most venereologists would be glad to dispense with these potentially toxic drugs. If consolidation treatment in early syphilis has any advantage, and this is generally denied in the United States, weekly injections of bismuth, or of procaine-penicillin with aluminium monostearate, or of both concurrently would seem to be safer and equally efficacious for this purpose. Be this as it may, a few weeks' consolidation treatment of any kind has the advantage of impressing the patient with the gravity of his disease and will underline the importance of adequate observation after treatment.

The accurate assessment of a new therapeutic agent in a disease so chronic and so protean in its manifestations, as well as in its reactions to treatment, is a difficult task. Prolonged and careful clinical observation and serological studies are important, but in addition that unpredictable element, the host factor of the individual patient, can never be neglected. It is easy to acclaim a dramatic cure or a failure of treatment, but more difficult to state dogmatically to what extent the treatment, or the lack of it, has been responsible for the result. It is only by careful observation of a large number of patients over a long period, and by careful comparison with the results obtained by treatment with the arsenicals, that we can even begin to come to a decision. Meanwhile the Syphilis Study Section of the National Institute of Health, of the United States Public Health Service, has been carrying out a carefully controlled experiment on a vast scale for more than three years. Up to the present these American workers are increasingly convinced with each succeeding year that penicillin alone with adequate surveillance is the best known treatment for early syphilis.

VITAMIN B_{12}

In previous annotations[1] we have commented on the isolation from large amounts of liver of minute quantities of a red crystalline compound containing cobalt and having great anti-pernicious-anaemia activity. This substance has also been isolated from fluids in which certain micro-organisms, notably *Streptomyces griseus*, have been grown.[2] Dunlop

and Wilson[3] in this country have recently reported good haematological responses in two cases of classical Addisonian pernicious anaemia, using extracts of the metabolism fluid of a strain of streptomyces. This encourages the hope that an alternative source of supply for the anti-anaemia principle may be developed, especially because of the present difficulty of obtaining livers of satisfactory quality. In addition, microbiological assay methods which have been developed during the isolation of this pure factor may eventually do away with the tedious necessity for clinical trial of all batches of anti-anaemia principle.

Many of the investigations carried out with folic acid are now being repeated with this new substance, hitherto known in the U.S.A. as vitamin B_{12} and now available commercially in that country under the trade name of "cobione." Spies and his co-workers, who have done much work on folic acid, have recently published their findings[4] in 21 patients with nutritional macrocytic anaemia, sprue, or pernicious anaemia. In all there was great improvement in the anaemia and also in symptoms such as sore tongue (though, as Brown[5] has recently shown, glossitis of this type may sometimes be relieved by substances other than the anti-pernicious-anaemia factor, such as calcium pantothenate, niacin, riboflavin, and folic acid) and in the abdominal discomforts of sprue. Improvements may occur after the injection of 10 μg. or even less, but it is thought that the optimal dosage may be nearer 100 μg. No information is yet available about the amount required to maintain a remission. In addition to these cases Spies treated with vitamin B_{12} 14 patients with pernicious anaemia complicated by subacute combined degeneration of the cord, and the symptoms due to peripheral nerve or posterior column involvement were much diminished. This finding, which confirms earlier reports, is in complete contrast with the effect of folic acid, which not only does not prevent development of neurological complications but in many cases appears to precipitate them. In macrocytic anaemia of pregnancy, however, the results were different. In a detailed account[6] from the Mayo Clinic a case of severe macrocytic anaemia occurring in the seventh month of pregnancy is described; the patient failed to respond to large doses of liver extract or to moderate amounts of vitamin B_{12}, but she improved immediately when folic acid was given.

Investigation of the relation of this new substance to Castle's intrinsic and extrinsic factors has yielded some unexpected results. In earlier trials vitamin B_{12} was given by injection, and its action appeared to correspond to that of the anti-anaemia principle thought to be formed by the interaction of the two factors and stored in the liver. However, a recent paper by Berk and other workers (including Castle)[7] records the effect of oral administration, with and without the addition of normal gastric juice, in cases of pernicious anaemia. By itself vitamin B_{12} had practically no effect, but in combination with 150 ml. of normal gastric juice 5 μg. of the substance led to reticulocyte responses of from 4 to 16% and increases of up to nearly a million red cells per c.mm. This type of activity is obviously similar to that of the extrinsic factor, and the question arises whether the intrinsic factor is some substance which merely facilitates the absorption of vitamin B_{12} without itself actually entering into the final composition of the anti-anaemia principle as has hitherto been believed. This view is supported by the finding by the same workers that commercial highly purified liver extract when given by mouth is likewise potentiated by the addition of normal gastric juice. Hall and his colleagues[8] have confirmed these findings, but point out that the quantities so far used have been small and that larger doses will have to be given before it can be stated unequivocally that vitamin B_{12} is without activity when given alone by mouth to patients with pernicious anaemia. Spies in the paper already cited also noted in one case failure of vitamin B_{12} to produce a response when given by mouth, though it was effective when given with gastric juice from an individual with duodenal ulcer. Apart from the theoretical importance of this finding, there is the practical conclusion that even if supplies of vitamin B_{12} become available for general use it will still have to be given by injection in the treatment of pernicious anaemia.

LUMBAR "FIBROSITIS"

Our correspondence columns have recently borne testimony to the lack of unanimity of opinion on the subject of "fibrositis." The clinical entity is well recognized, but pathologically it probably represents a composite group of abnormalities; when no definite lesion is demonstrable some would prefer to talk simply of "myalgia"—an adequately descriptive term which makes no pretension to deeper understanding. From the whole group of patients with this symptom complex Copeman and Ackerman[1] have recently separated those in whom lumbar and gluteal fat herniation gives rise to backache and referred pain in the leg. Dissecting the cadavers of previously healthy soldiers, they constantly demonstrated the presence of deposits of fibro-fatty tissue beneath the superficial fascia in well-defined areas along the outer borders of the sacro-spinalis and above the crest of the ilium. This constant localization of fat they termed the "basic fat pattern." In certain areas there were small fat herniations through the fascia, particularly where it was pierced by the cutaneous branches of the lumbar nerves and their accompanying blood vessels.

We published in July an article[2] in which Copeman discussed the significance of these findings in relation to certain "rheumatic syndromes." In cases of lumbar myalgia there were local tender nodules, pressure on which reproduced the pain. The distribution of these "trigger areas" corresponded with that of the "basic fat pattern." Excised nodules were seen to consist of oedematous fibro-fatty tissue herniated through the fascia and continuous with the underlying deep fat. Relief of pain followed excision or disruption of the nodule by injection of 10–20 ml. of procaine, followed by extensive teasing and undercutting with the needle-point. Copeman and Ackerman claim that the demonstration of these lesions provides scientific justification of the customary treatment of "fibrositis" by heat, massage, and movement, because these procedures improve the blood

1 *Arch. intern. Med.*, 1947, 79, 22.
2 *British Medical Journal*, 1949, 2, 191.
3 *J. Urol.*, 1948, 59, 1061.

supply and lymphatic drainage and help to destroy the nodules or reduce the herniation. They are careful to point out, however, that this abnormality is not present in all cases of myalgia. The frequent indiscriminate use of physiotherapy for backache can lead only to much waste of effort and eventual disappointment, particularly when the disability is primarily psychoneurotic or postural in origin.

Orr, Mathers, and Butt,[3] confirming Copeman and Ackerman's work, have demonstrated the presence of nerve fibres in the tender fibro-lipomatous nodules excised from the lumbo-dorsal region of patients who complained of pain which simulated that of uretero-renal disease and in whom no urological disease was found. In each case removal of the nodule effected cure. This series illustrates the need for caution in the interpretation of pain arising from deep structures. Sensory impulses from superficial tissues can be accurately localized, but, since the deeper structures are poorly represented in the sensorium, pain arising therefrom is felt diffusely throughout the corresponding spinal segment, so that visceral disorders may be suggested by pains arising from somatic structures, and vice versa. Not only fat herniations but also other musculoskeletal disturbances such as old, unnoticed crush fractures, Pott's disease, disk prolapse, and soft-tissue injuries may mimic visceral disease and lead the unwary to recommend unnecessary investigations and even repeated and unsuccessful visceral surgery, particularly when pain is referred to the abdomen. There is also the danger that musculoskeletal derangements causing ill-localized pain may all too easily be diagnosed as "fibrositis" or "muscular rheumatism."

MOUSE CANCER TREATED BY STREPTOTHRIX CULTURE

There have been many attempts to influence the growth of transplantable tumours of the mouse by injecting the products of growth of micro-organisms—from the toxins of streptococci to those of *Trypanosoma cruzi*. Although favourable results have been claimed, usually the products have proved either too toxic or too erratic in action to prove of value. A recent report comes from de Angelis,[1] who claims that the culture fluid of a mycete originally isolated from granulomatous lesions in a cat, and hence called *Streptothrix felis*, has a specific action on tumour cells. The exact method of preparing mycetin, as the active product is called, is not disclosed, but it appears to be a sterile neutral filtrate of cultures of the streptothrix. In mice the highest tolerated dose injected subcutaneously is 0.4 ml. Sometimes only one subcutaneous injection, at other times two or three, were required to bring about a cure; the injections were made as far away as possible from the site of the tumour. De Angelis chose the adenocarcinoma of Ehrlich as the experimental tumour, and the results he reports are certainly startling. Of 106 mice treated 12–14 days after transplantation of the tumour 102 were completely cured and four died from causes unconnected with the experiment; all the control mice, of which there were 102, died. When the tumours were allowed to grow larger—from 15–20 days after transplantation—injections of mycetin cured 112 of 116 mice; two died from an accident, and in two there was no absorption of the growth. Of 98 controls, all died. One hundred and eight mice with tumours of greater age were treated: 94 were cured, four died with a reduction in size of the tumour, and 10 were unaffected. Thus the results were successful in 93% of all the mice treated (330). Mice which had been cured were resistant to further inoculation with the same carcinoma. In interpreting experiments on transplantable mouse carcinomata it must always be remembered that damage to the tumour and consequent absorption may be due not to direct damage to the cancer cells but to interference with the blood supply of the actively growing tumour cells—haemorrhage leading directly to cell necrosis. No attempt seems to have been made to determine whether or not mycetin acts directly on tumour cells or on the blood vessels of the carcinoma.

THE DEVALUED POUND

Though Sir Stafford Cripps dwelt on the increased cost of wheat, and therefore of bread, as a consequence of the devaluation of sterling, which he announced on September 18, he mentioned briefly that "dollar goods . . . will cost more in pounds, shillings, and pence." Among these we suppose will be a number of drugs and raw materials used in medicine which are imported from hard-currency areas. They include cascara sagrada, which is derived from the California buckthorn; senega, the dried senega snakeroot of North America; valerian, which is imported from Belgium, though the plant from which it is extracted grows wild in Britain; and hamamelis, from the Virginia witch-hazel. The balsams of Canada, Peru, and Tolu (in Colombia) may cost more, as well as the oils of chenopodium, turpentine, and sassafras. If molasses goes up in price, acetic acid, ethyl acetate, and amyl acetate, which are derived from it, may follow suit. Bismuth, mercury, and silver are also imported from America, and we may have to pay more for olive oil, which comes from Italy, since we shall be competing with hard currency to buy it. Aureomycin is still obtainable only from the U.S.A. Presumably the price of American books and journals will increase, and possibly that of some cotton used in dressings. It seems even that we can hardly take comfort in the thought that the price of tobacco will rise and thereby deter some of our patients from poisoning themselves so heavily, for the cost of the American tobacco in cigarettes is so small that it contributes very little to the price of the finished article.

Since the pound is now equivalent to $2.80 instead of $4.03, American goods will cost about 30% more—that is, in the words of Sir Stafford Cripps, "if dollar prices do not fall." Speculation on the rate of international exchange and the price of gold may be left to the economists, who are better equipped to pronounce on a subject where—to misappropriate a maxim of Bernard Shaw's—the golden rule is that there are no golden rules. But it seems possible that the cost of the Health Service will rise slightly in the next few months unless alternative sources can be found from which to import a number of materials essential to medicine.

FOURTH INTERNATIONAL NEUROLOGICAL CONGRESS

MEETING IN PARIS

[FROM A CORRESPONDENT]

The fourth International Neurological Congress was held in Paris from September 5 to 10, under the patronage of the President of the French Republic and of the French Foreign Ministers. The president of the Congress was Professor T. Alajouanine, of Paris, and the senior vice-president Professor J. A. Barré, of Strasbourg. Sir Charles Sherrington and Dr. Gordon Holmes were the British *présidents d'honneur*, and Dr. Anthony Feiling the British vice-president. A national committee had been set up in each of the participating countries to prepare the programme, and the four official languages were British, French, Spanish, and Russian. Great credit is due to the French neurologists and officers of the Congress both for their skill in organization and for their hospitality to the many overseas representatives who attended.

The late summer was at its finest in France as in England, and the many scientific meetings took place under conditions of most oppressive heat, made all the worse by the necessity to close and darken the lecture-rooms of the School of Medicine when showing slides. The neighbouring cafés were thronged through the day with distinguished neurologists of all nations refreshing themselves and recovering between sessions. The Congress opened with an evening reception by the president and members of the French Society of Neurology. French social occasions have a delightful informality unfamiliar in this country. Those who attended found no reception at all in the sense of having to queue up and be received before enjoying the excellent hospitality. It was as well on so hot a night that with the minimum of delay life could be preserved by bumpers of iced champagne.

On Monday, September 5, the members of the Congress were welcomed to Paris by the president, M. Pierre de Gaulle, brother of the general, and the members of the Municipal Council at a crowded gathering in the Hôtel de Ville. The social occasions of the Congress concluded with the official banquet on Friday. There was only a short speech from Professor Alajouanine, presiding, and a brief acknowledgment from the veteran Professor Austregesilo, of Brazil, with none of the prolonged post-prandial oratory commonly inseparable from such functions in Britain.

Many short papers on a wide range of subjects were read. Longer papers were devoted to electroencephalography and electromyography, the thalamus and its pathology, the surgery of pain, and virus diseases of the nervous system. Some of the more important points in the discussion on this last subject were reviewed in an annotation last week (*Journal*, September 17, p. 643).

Electroencephalography and Electromyography

Dr. Frédéric Bremer (Brussels) presented a report upon the physiological basis of electroencephalography in which he discussed the origin and significance of cerebral electrical rhythms.

Dr. Herbert H. Jasper (McGill University), speaking on electroencephalography in neurosurgery, emphasized that the most important application of E.E.G. was in the investigation of epilepsy. Second in importance was its use in estimating the severity and location of damage in cases of head injury. He placed third its employment in locating expanding intracranial lesions (he considered air-encephalography more reliable). Fourth came its diagnostic applications in vascular, infective, toxic, and degenerative lesions. Dr. Jasper gave in detail his findings in the different forms of epilepsy. With cerebral tumours and abscesses, he considered that in expert hands location could be achieved by E.E.G. in 80–85% of cases.

"The most important advance of interest to the neurosurgeon is the perfection of methods for recording electrical activity directly from the exposed cortex (electrocortigrams) and from subcortical structures (electrothalamograms). Finally, with the intimate collaboration of neurosurgeon, neurologist, neuro-anatomist, and neurophysicist, the brain is being induced to reveal its secrets through a study of its electrical actions."

Of current investigations now being carried out in various laboratories the most important were studies of the functional anatomy of the thalamo-cortical projection systems, which played such an important part in regulating the electrical activity of the cortex.

Dr. Denis Hill reviewed the electroencephalographic concept of psychomotor epilepsy, emphasizing its protean causations.

Dr. Fritz Buchthal (Copenhagen) gave a wide survey of electromyography, with diagrams of central and peripheral lesions of the nervous system. He considered the electromyogram an important aid in the differentiation of neurogenic from intrinsic muscular paresis or atrophy. It was often the only way of deciding whether interruption of a motor nerve by injury was complete or not.

Professor W. E. Le Gros Clark (Oxford) introduced the subject of the thalamus and its pathology with a summary of the present state of anatomical knowledge. He referred to increased knowledge of the direct anatomical connexions between different thalamic nuclei and functionally distinct areas of cortex, and drew attention to our ignorance as yet of the significance of this in differentiating the functions of the various thalamic nuclei. Dr. W. R. Hess (Zurich) gave a parallel report upon thalamic physiology, and Van Bogaert (Amsterdam), Lhermitte (Paris), and others contributed clinical studies of thalamic problems.

Virus Infections

Professor A. B. Sabin (Cincinnati) discussed the classification of virus infections. Virus diseases in man were divisible into two broad groups: those due to a virus having its basic reservoir in human beings, and therefore world-wide in distribution; and those due to viruses whose basic reservoir was extra-human, with consequent variations in distribution in the world. The most important virus in the first group was that of poliomyelitis; others in this class were herpes simplex and lymphogranuloma venereum.

Of the viruses with an extra-human basic reservoir there was the large group of arthropod-borne encephalitides, and the group of viruses transmitted to man by the secretions or excreta of animals—e.g., rabies and lymphocytic choriomeningitis. To these two classes of virus must be added a third, that of diseases such as encephalitis lethargica in which the virus had yet to be isolated. Dr. Sabin differentiated neurotropic from neuronotropic viruses, the latter having the power of multiplying within neurones and being able to pass synapses. A feature of virus infection in man was that only a small proportion of those infected ever showed symptoms.

Professor W. McD. Hammon (University of California) gave a detailed account of research into the epidemiology of arthropod-borne viruses and expounded the theory that their true reservoir, in which they survived, was the mite, though they had in the U.S.A. various secondary hosts, such as birds and horses.

Dr. Sven Gard (Stockholm) discussed the virus of poliomyelitis. He described the discovery of a group of viruses closely related to that of poliomyelitis, and referred to the occurrence of myocarditis in this disease—a subject requiring further study.

Dr. Lépine (Institut Pasteur) spoke about the viruses of herpes, choriomyelitis, and rabies; and Dr. G. M. Findlay (London) discussed factors influencing infection of the C.N.S. by viruses.

Neurosurgery and Thymectomy

There was a masterly report on the surgical section of pain tracts and pathways in the spinal cord and brain stem by Olaf Sjöqvist (Sweden), covering all aspects of the subject. Case reports of prefrontal leucotomy and lobectomy for intractable pain came from Dr. Krayenbühl (Zurich), and Professor René Leriche (Paris) surveyed the whole field of surgery of the sympathetic system for the relief of pain.

Mr. G. F. Rowbotham (Newcastle) described his experience over many years in the surgical treatment of migraine and gave his case results. He had practised various procedures, singly and in combination, such as trigeminal root section, section of the middle meningeal artery, cervical sympathectomy, and division of the external carotid artery. He advised, in cases of frontal headache, division of supraorbital and cervico-temporal

arteries in the scalp, and of the middle meningeal artery and petrosal nerves intracranially. Later, if necessary, trigeminal tractotomy might be performed, or even sympathectomy.

Dr. Henry R. Viets (Massachusetts General Hospital) described the results of thymectomy in 36 patients operated on since 1941. Seven of these patients had thymomas and three of them were still living. One had survived six years and the other two were greatly improved after operation. All but four of the 29 patients with myasthenia gravis and with no thymic tumour had survived. The results were excellent in five, good in five, fair in four, and poor in four. It was too soon to estimate the results of operation in the remaining seven cases. He urged that patients should be adequately maintained on oral neostigmine before operation, and neostigmine might with advantage be given intravenously during thymectomy. The significance of germinal centre formation in the thymus was not clear, but the finding of a large number of germinal centres was highly suggestive of myasthenia gravis. In his view the results obtained by thymectomy over the last nine years justified the continuation of the operation in the treatment of myasthenia gravis.

Shorter communications were very numerous, covered a wide range, and attained a high standard of interest and originality. Mention should be made in particular of Dr. S. P. Meadows's (London) paper on carotid cavernous aneurysms and pulsating exophthalmos, and that of Dr. A. G. Frovig (Oslo) on the syndrome of bilateral obliteration by arteritis of the common carotid artery.

On Saturday, September 10, at the last session, Dr. Pearce Bailey (Washington) reviewed the difficult position of neurology in the U.S.A., sandwiched as it was between neurosurgery and psychiatry, and he urged more active organization amongst neurologists.

ANNUAL CONGRESS OF PHYSIOTHERAPISTS

AN EXPANDING PROFESSION

The annual congress of the Chartered Society of Physiotherapy was held at St. Pancras town hall from September 14 to 18. Each day was fully occupied with a programme of lectures, demonstrations, and hospital visits, and the members were entertained at receptions by the Royal College of Physicians and by the Council of the Society.

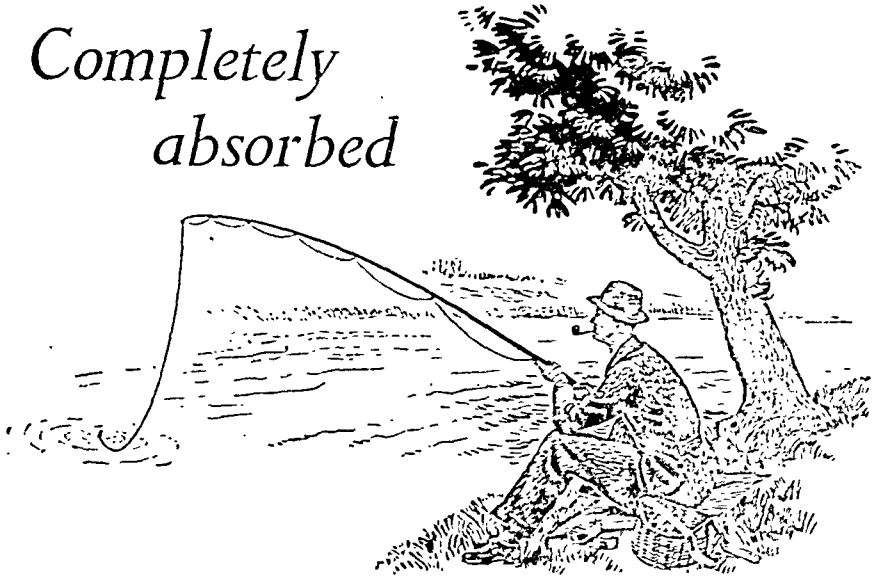
The opening lecture was given by Dr. J. A. CHARLES, Deputy Chief Medical Officer, Ministry of Health, with Dr. W. S. C. COPEMAN, chairman of council, presiding. Dr. Charles reviewed the developments in health services and social insurance in various countries. The beginnings of social insurance in France, he said, could be traced back to the immediate post-revolution period. Virtually the entire population of France was now included in social insurance schemes, contributions to which represented up to 16% of income. The fee payable for a consultation was variable: one rate for a general practitioner, double for a specialist, treble for the member of a teaching staff of a hospital, and the rate varied again according to region. The French regarded their system, despite its large staff of functionaries, as less bureaucratic than ours. Direct payment of fees by the patient was considered to be a great bulwark against a salaried service. The doctor charged the patient according to an official tariff, and the patient was reimbursed up to 80% from the fund. Capitation fees were anathema to the French doctor.

In Sweden the basis of medical care was twofold: organized sickness insurance within a circumscribed field and a magnificent hospital system. Sickness insurance would next year become a compulsory system covering the entire population. The patient paid the doctor and recovered two-thirds of the expenditure from the sickness fund. Sweden's great problem was shortage of doctors. Medical fees were moderate by our standards, but on the average doctors were well up in the highest income levels, their scarcity increasing their power as a pressure group. It was proposed to open new medical schools. With regard to the United States, Dr. Charles gave some figures comparing maintenance costs in the same 14 hospitals 60 years ago and now; the average daily maintenance cost per patient in the 'eighties was 1 dollar 39 cents; to-day it was 14 dollars 61 cents. Nearly one million new hospitals beds were needed in the United States.

Coming finally to this country, Dr. Charles claimed that the National Health Service had proved popular beyond all expectation: 95% of the people had chosen their general practitioner; the indexes kept by executive councils included names from every class of the population, and 95% of doctors, 90% of dentists, and practically all pharmacists were in the Service. The overall cost of the service for England and Wales was £232 million in the present financial year, roughly 2s. 1d. per head per week. It might be that within this field there was a possibility of saving here and there, but the cost must be viewed against the background of the £300 million a year lost to industrial production on account of illness. The benefits which the Service would bring, used wisely and intelligently, were tremendous.

Physiotherapy and Chest Surgery

Mr. T. HOLMES SELLORS lectured on "Physiotherapy in Chest Surgery." The subject, he said, was one which had been specially developed in this country; it was not practised at all widely in other countries he had visited. In chest surgery the association between the surgeon and the physiotherapist was very close. The surgeon was completely dependent on good physiotherapy for the operative preparation of the patient and for restoration to health and posture after operation. He regarded the physiotherapist as an essential member of the team. Many people in hospital were quite prepared to carry out physiotherapy, but the results were not satisfactory. An extremely high standard was demanded and was achieved in special chest units and hospitals only where physiotherapists were engaged in this type of work for practically the whole of their time. It took from four to six months for the physiotherapist to master chest practice. Any general hospital—he was not now speaking of a special chest hospital—which had 100 or 150 beds would provide nearly enough in-patient and out-patient work to occupy one physiotherapist.



On the admission of the patient the physiotherapist must study his respiratory capacity, and then institute breathing exercises appropriate to the type of treatment which was going to be undertaken. Patients with low vital capacity and stiff chests could be educated in two or three weeks and made "safe for surgery." Chest surgeons prided themselves on the fact that their post-operative complications were fewer than in general surgery, and for this result thanks were due to the physiotherapist. Expiratory exercises played little part in chest surgery except in such conditions as asthma and in squeezing out secretions from the lung in bronchiectasis. It was inspiratory effort that was emphasized, and this not just a diffuse movement, like a general heave of the chest, but a controlled localized movement. A patient, if intelligent, could be trained to move one part, and one part only, of his chest.

The physiotherapist must always be aware of the rate at which chest deformity could develop. It called for concentrated effort on the part of the physiotherapist to transmit her enthusiasm and persistence to the patient. There was great value in the psychological stimulus that she could give. Liaison between the physiotherapist and the occupational therapist, again, could be very valuable. Mr. Sellors went on to describe various chest conditions and the work of the physiotherapist in regard to them. After an operation such as thoracoplasty in a female patient it was possible to maintain the patient's posture so that although the chest was flattened above and below, unless she wore evening dress, no deformity was visible.

New Hope in Rheumatoid Arthritis

In another lecture Dr. W. S. TEGNER discussed the present situation in regard to rheumatoid arthritis. The theory of a septic focus was dying hard, but it had never been possible to isolate a toxin capable of producing rheumatoid arthritis. The theory of sensitization and allergic response had been formulated but never proved. An American report suggested that in every group of sufferers one-fourth recovered, one-fourth

Completely absorbed

Gelatin Sponge A & H, a sterile absorbable hæmostatic, has applications in all branches of surgery, from the simple epistaxis encountered in general practice to the more complex operations of neurosurgery.

It minimizes blood loss when adequate hæmostasis cannot be obtained by ligature, and will help to increase the safety of operative surgery in many fields.

Gelatin Sponge A & H is pliable and may be moulded easily to any shape or size to meet the requirements of the occasion.

Supplied sterile in glass containers in strips 2 cm. × 6 cm. × 0·7 cm., in boxes of six tubes each containing one piece, and thin wafers 2 cm. × 2 cm. × 0·1 cm. in boxes of six tubes each containing 6 pieces.

GELATIN SPONGE A&H

An absorbable hæmostatic

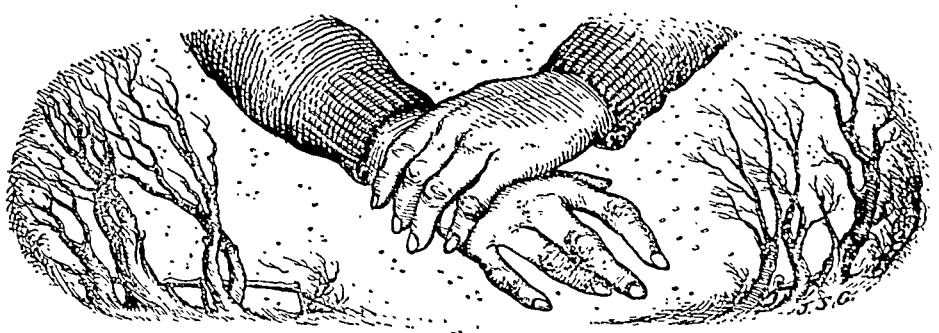
pure thyroid hormone:

new synthesis

Recognising the need for a standard form of thyroid medication, capable of being given in precise dosage, Glaxo Laboratories have carried through a research project to evolve an entirely new synthesis of the thyroid hormone. Success has now come in far greater measure than was at first envisaged, for the process ultimately devised has made it possible to manufacture the physiologically active *laevo* thyroxine free from the inert dextroform.

a new era opens in **thyroid therapy**



L-Thyroxine-sodium *Glaxo*, now introduced is the pure *crystalline thyroid hormone*. By its very nature, it is free from the variations in therapeutic efficacy that may be associated with extracts of the thyroid gland. Relative potency is indicated by the fact that about 1 grain of thyroid B.P. may now be replaced by 0.1 mg. of the new Glaxo material.

'PERNIVIT' FOR CHILBLAINS

Tablets of Acetomenaphthone B.P. and Nicotinic Acid B.D.H.

The comparative ineffectiveness of single substances in the treatment of chilblains suggests that the condition results from the interaction of more than one factor. A new approach has been made possible by the introduction of 'Pernivit' which facilitates the utilisation of the vasodilator effect of nicotinic acid and the effect of vitamin K in maintaining normal vascular permeability and blood coagulability. A dose of from three to six tablets daily is recommended. Bottles of 50 and 500 tablets.

Literature and samples will be forwarded on request

became crippled, and half had a long period of exacerbations and remissions. Another American report put the recoveries at only 15%. Starvation, surgical operation, and anaesthesia had a favourable effect on the disease, but more surprising was the ameliorative effect of obstructive jaundice and of pregnancy.

A specific treatment which had long been advocated was by intramuscular injections of gold. The claims made for gold therapy were unjustifiably optimistic. Hench had found the improvement after gold therapy to be far less than the improvement during an attack of jaundice or during pregnancy.

The lecturer then described the work carried out on "compound E." or "cortisone." He had seen some of the patients treated in America and had never seen such rapid cures or remissions. It could certainly be said that a rare and expensive product had been found which profoundly altered the pattern of the disease. The patients responded to it physically and mentally in a remarkable manner. The psychological effect was to produce a euphoria which was more than the effect of well-being after recovery from illness. There was need for a dispassionate survey of the results of this discovery and of the relation of cortisone to the aetiology of rheumatoid arthritis. Every effort must also be made to produce cortisone economically at reduced cost. There was no evidence that it had any value in osteoarthritis. The speaker also uttered a warning against all sorts of "pseudo-cortisones" which were springing up. He believed that the introduction of the real cortisone would bring about the rapid disappearance of other specific treatments, including gold, and he hoped it would not be long before supplies were available in this country, but care must be taken that it was not wasted on the wrong patients.

Physiotherapy in Obstetrics

Lectures accompanied by films and lantern demonstrations were given by Dr. Dudley Hart on ankylosing spondylitis; by Mr. L. W. Plewes on industrial rehabilitation; by Dr. Griffith Pugh on the effects of cold on the human body, and Dr. J. T. Ingram on the health of the skin. Dr. E. J. Crisp gave a survey of the present-day scope of ultra-violet irradiation.

The role of the physiotherapist in the training of the expectant mother was the subject of an address by Professor W. C. W. NIXON, and was followed by a demonstration of exercises in which patients from the Royal Free Hospital participated. Professor Nixon said that in surgery the physiotherapist had played a conspicuous part in preserving and restoring normal function. Formerly the masseuse was looked upon as an intruder. It had taken time to convince the surgeon about the possibilities of physiotherapy, but now the physiotherapist had been recognized as playing a necessary part not only in post-operative but in pre-operative care. In obstetrics the physiotherapist had started her work in the post-natal period, but from that it was a short step to antenatal physiotherapy. She had an important role to fulfil in training the woman for her confinement, including the preparation for the actual delivery. This was what should be regarded as the greatest athletic event in a woman's life, and for any athletic event training was necessary. The mothers had been quick to respond. Instead of paying rather half-hearted visits to the antenatal hall they had, thanks to the physiotherapist, come to feel that something definite was being done for them. Too often in the antenatal clinic the accent had been on the abnormal rather than on the normal. The physiotherapist restored the balance by presenting the physiological aspect of pregnancy and making it real through a series of antenatal exercises. Instead of being passive examinees, the expectant mothers became active participators. Who could teach relaxation better than the physiotherapist? Those who had the care of expectant mothers knew that the great problem was to eliminate fear, and this was most successfully done by proper training during pregnancy. Physiotherapists had done much to bring home to mothers the idea that labour was a normal process, and to evoke that confidence which made for a happy labour. He thought that physiotherapists should be given the privilege in the labour ward of seeing the results of their instruction.

Causation and Prevention of Deformity

The Founders' Lecture was delivered on the last day of the Congress by Sir HARRY PLATT, who discussed the causation and prevention of deformity. Deformity, he said, was formerly accepted as the inevitable accompaniment of many accidents and diseases, but now the emphasis was on prevention, and in such prevention the physiotherapist played an important part. Acquired deformity might be most conveniently studied in the form of joint contracture, of which he distinguished three main clinical types—namely, the contractures of flaccid paralysis, those of spastic paralysis, and those which resulted from intrinsic changes in the muscles. Taking as an example the contractures in poliomyelitis, he said that these were initiated by a state of muscle imbalance in which the active muscles began to shorten. Such contractures in poliomyelitis might occur within the first few weeks after onset. They were in general not difficult to prevent. In the majority of orthopaedic hospitals and clinics the old practice of rigid immobilization in the early stages of poliomyelitis had been abandoned. The limbs were now supported in correct postures, and as soon as they could be handled without distress the joints were treated by physiotherapeutic methods, so that by the time the patient was on his feet no contractures should be present.

It must never be forgotten in poliomyelitis, however, that throughout the recovery stage the tendency to contracture remained. When the patient began to walk other deforming influences were added—growth, gravity, posture, counter-resistance, and so on. The physiotherapist in charge of a re-educational programme should be constantly on the look-out for deformities such as lateral curvature of the spine or inversion of the foot, or claw foot. Perhaps the most difficult problem in poliomyelitis was to prevent or control lateral curvature of the spine, which might be established during the first few weeks after onset or might develop gradually in the first year with a spine in which the equilibrium had appeared to be normal. The spine needed to be watched until growth was finished, because the deforming forces of asymmetrical posture and attitude might continue during the whole period of growth.

In tuberculous disease, again, particularly in children, the joints must be protected from deforming influences long after the disease itself had apparently subsided. The contractures in rheumatoid arthritis were of the usual gravity-aided type, modified occasionally by extreme malposture. The joints usually required a short period of rest and fixation, succeeded by purposive mobilization, still under adequate mechanical control. Finally, Sir Harry Platt touched upon the contractures in elderly bed-fast patients—contractures which it was now seen could and should be prevented. The rehabilitation of the aged was a challenge to social medicine.

Physiotherapy under the Act

Lord HORDER, president of the Society, was in the chair at the dinner, which was the closing event of the Congress. In proposing the health of "The Guests," he referred with regret to the fact that at the last moment the Minister of Health, who was expected to be the principal guest, had been detained by important Government business. Sir WILSON JAMESON, Chief Medical Officer of the Ministry, who came in his stead, described himself as a "simple-minded, ingenuous doctor, and a mere Civil Servant," no substitute for his colourful chief. What was now called medical rehabilitation, Sir Wilson Jameson continued, was no single-handed job; it required the collaboration of a number of people—doctors and nurses, physiotherapists and social workers. That was why the Ministry had adopted the policy of making physiotherapy part of the hospital and specialist services. He knew that there were good arguments for making it part of the general practitioner service, but it was not practicable to do this. There was a shortage of physiotherapists, and therefore it was necessary to use them where maximum facilities were at hand and where man-power could be economically employed. But the Minister had sent to regional boards a circular asking them to extend services to small towns and villages where necessary and in certain cases to afford domiciliary treatment. Thus he hoped that in

course of time the service would be extended, and that quite a number of physiotherapists would be able to take up part-time clinic service and so be compensated for any loss of private practice which the National Health Service had brought about. If there was a shortage of physiotherapists there was no shortage of applications for training; the difficulty was non-availability of premises and lack of teachers. Speaking of the Health Service as a whole, Sir Wilson Jameson said that it had been with them for a year and would be amended in the light of experience. It would never be a success unless there was willing co-operation on the part of those who worked it and of the public for whose benefit it was established. There was great need for the education of the public in the economic use of the Service. "There is a limit to what the country can afford—even for health."

The health of the Society was proposed by Sir HARRY PLATT, who, in sketching the future of physiotherapy, prophesied increased specialization. In the great hospital departments specialization must be the rule. The toast was responded to by Dr. W. S. C. COPEMAN, chairman of council, who said that in 1920, when the Society acquired its charter, the membership was 6,070; it was now 17,333. He spoke of his recent visit to the United States, where he had found physiotherapy not as fully recognized and developed as in this country, but training facilities, research fellowships, and physiotherapy departments in teaching hospitals were now being extended.

Nova et Vetera

THE M.R.C.P.

From early in the sixteenth century to 1858 the London teaching hospitals usually required their physicians or assistant physicians to be Fellows or licentiates of the Royal College of Physicians of London. This was indeed a legal obligation, because the College had a monopoly of licensing physicians to practise in or within seven miles of London. In 1858 a Medical Act abolished the monopoly, but the custom of the hospitals continued with a merely verbal change—the substitution of "member" for "licentiate." After 1858 the College assigned the word licentiate to a qualification granted on wholly different terms from those imposed on the old licentiates, but granted a diploma of membership on the old terms—namely, a rigorous examination by the Board of Censors.

In the eighteenth and even early nineteenth centuries the College was a small body. In 1817 there were 89 Fellows and 224 licentiates. It is now more than ten times as large. In 1948 there were 747 Fellows and 2,691 members. Through the last half of the nineteenth century growth was comparatively slow, because College by-laws forbade Fellows or members to dispense medicines or practise in partnership. Early in the present century members were freed from these restrictions, and their numbers increased. In July, 1938, there were 161 candidates for the membership examination. After the war the number increased sharply; in July, 1948, there were 596. Every reader knows the reasons for this, knows why just four short of the gallant six hundred charged the guns of Pall Mall East a year ago and sustained, in a Pickwickian sense, as heavy casualties as the heroes of Balaclava.

Medical correspondence columns have recorded differences of opinion on the merits of this examination. Thus under the present regulations any holder of the M.R.C.S., L.R.C.P. diploma or graduate in medicine of a recognized university may submit himself for examination four times a year on payment of a fee of ten guineas and may continue to do so until his patience, or his money, is exhausted. The College, very wisely, appointed a strong committee to inquire into the position, and their report (discussed in an annotation in the *Journal* of August 6, p. 327) is an interesting document. It would have been even more interesting to the historically minded had a comparison been made between the examination of, say, 40 years ago and what it now is. Now, as 40 or 100 years ago, the whole responsibility rests on the President and Board of Censors. It is certain that in one respect the examination has been modernized. Down to 1924 the censors encouraged, or tolerated, a belief that physicians should be acquainted with the learned languages; candidates were required to attempt to construe a passage in Greek or in Latin. But in 1924 a candidate—a lady whose clinical marks were brilliant—eschewed both classical questions; she was therefore subjected to a special interrogation by the President and, having correctly construed pons varolii, approved. The registrar of that day, an excellent scholar, suggested, with the meiosis lovers of Horace usually display, that such a test verged on the farcical; so obligatory Latin (or Greek) was eliminated, and, perhaps, the censors of the eighteenth century turned in their graves.

ASPECTS OF LEUCOTOMY

U.S.A. SYMPOSIUM IN LONDON

The presence in this country of a number of American psychiatrists returning from the fourth Congress of Neurology at Paris was made the opportunity for calling a special meeting of the Section of Psychiatry of the Royal Society of Medicine on September 12 and 13. The chairmen at the four sessions were Dr. J. R. REES, Dr. W. REES-THOMAS, Sir HENRY DALE, and Professor F. L. GOLLA.

Theoretical Considerations in Brain Surgery

An opening paper on the theoretical aspects of frontal leucotomy and similar brain operations was read by Dr. PAUL H. HOCH, of New York City. From observations on patients who had undergone operation he concluded that the basic intellectual and emotional life of the individual, necessary for the functioning of his personality, was not located in the frontal lobe alone but distributed over the cortical areas and in the corresponding thalamic regions. It was nevertheless possible that the highest functions, such as creativeness, planning, and fusion of intellectual and emotional performance, were to be ascribed to the frontal lobe. The diffuse distribution of psychic functioning in the thalamus and cortex did not mean that the brain always acted as a whole but that these functions were distributed and safeguarded by diffusion all over the cortex. There were concentrations of function in certain areas, which areas could interfere more than others with psychic activity, but the view that elementary intellectual and emotional functioning could be located in certain areas, and that there were centres for basic personality traits and drives, was not tenable. Alterations of personality could be brought about by ablating the cortex, operating on the thalamus, or by cutting the connexions between the thalamus and cortex. To achieve therapeutic results it was necessary to remove a certain amount of cortex or to interrupt a certain proportion of cortico-thalamic connexions. If not enough pathways were cut or not enough cortex was detached, no improvement would result; if too much was done, marked personality damage was produced. Professor Hoch added that he did not want to convey the idea that other factors did not enter into personality changes, but he believed that the quantitative factor, especially in relation to pathways or connexions, should be carefully studied and evaluated.

He also devoted some attention to the problem of changes in personality which attended the operative results. Clinically the most conspicuous impairment was a certain inertia or apathy. The patient showed no sustained effort, no drive to creative achievement, no foresight. A "don't care" attitude developed. The depth of emotional experience was reduced and social sentiments often impaired. These personality changes, which were not always permanent, were, he believed, due principally to the elimination of anxiety, tension, and ego awareness. "Our society is built on a certain amount of anxiety. Without it, no socialization of the human being would be possible." Anxiety,

sublimated, performed as creative energy. The elimination of this anxiety involved personality damage.

"However, this does not mean that brain damage is absolutely necessary to achieve results, though some maintain this view. We do not know the optimum operation yet. It is possible, as some of the recovered cases indicate, that the operation can be balanced well between symptom-reduction and damage. In most instances to-day we probably damage more than necessary. Our present methods of operation are crude and not reliable, but the question is open, and will have to be investigated further."

It was possible, in his opinion, to relieve the patient of his symptoms and not inflict a great deal of damage to the personality. Successful transorbital lobotomies indicated this clearly. With more knowledge of what amount of cortex should be detached or what pathways should be cut an ideal operation was conceivable which would cure without impairment.

Safety and Effectiveness of Leucotomy

Dr. WALTER FREEMAN, of Washington, said that safety and effectiveness were the two main considerations in choosing an operation for the relief of mental disorder, but accuracy was coming to be an important feature, and availability was also stressed in view of the large number of patients who were being considered for psychosurgery. Safety had already been achieved in large measure. The various operations on the frontal lobes had never carried as high a mortality as 10% in any considerable series; usually the mortality had been about 3%, and some teams claimed 1% or less.

Effectiveness was largely dependent on the psychiatrist. Brazilian psychiatrists apologized for poor results, stating that only the most chronic and deteriorated patients were operated on. The English Board of Control, in publishing in 1947 the results of 1,000 leucotomies, found a direct relationship between the duration of the psychosis and the results of operation. Topectomy had brought precision to operations upon the frontal lobes in that symmetrical areas had been removed. Research had shown that most leucotomies were unnecessarily extensive. The selective leucotomy used largely in England was also proving the value of limited operations.

Dr. Freeman said that he and J. W. Watts had studied the plane of section in relation to social effectiveness, and had found the following: "Incisions made 10 mm. behind the sphenoidal ridge would, in most instances, relieve a severe chronic psychosis and enable the individual to engage in a simple occupation. Incisions 15 mm. or more behind the sphenoidal ridge result in helpless invalidism. Incisions anterior to the sphenoidal ridge permit the patient, if relieved of his psychosis, to engage in constructive work and also to enjoy recreational, social, and intellectual pursuits."

Leucotomy and Shock Therapy

A comparison between psychosurgery and shock methods was given by Dr. LOTHAR B. KALINOWSKY. The indications for the two procedures, he said, did not overlap as often as might be expected. In most cases shock treatments could be applied to the utmost before surgery was considered, but there were many other cases in which shock therapy was not indicated. Selection of patients for psychosurgery was one of the most responsible tasks for the modern psychiatrist. It was a new challenge to them to revive objective means of diagnosis, to adhere to a well-established terminology, and thus to arrive at a diagnostic grouping resembling so far as possible the diagnostic methods in other fields of medicine.

After a long discussion on what constituted adequate shock treatment, Dr. Kalinowsky went on to claim that there was no evidence that previous shock treatment added to the hazards of surgery. No relation between convulsive therapy and post-operative convulsions must be assumed; convulsive therapy did not predispose to epilepsy, and was even used in its treatment. Schizophrenics who failed to respond to shock therapy fell into three groups: those who for some reason failed to respond although they belonged to a category of schizophrenia which usually responded well; those who offered poor prospects for any treatment; and those for whom shock treatment was scarcely indicated. Patients in the first of these groups should be submitted to surgical treatment rather early before deterioration set in. For those in the second group, mostly hebephrenics, psychosurgery should rarely be recommended; their clinical level might be temporarily improved by an occasional E.C.T. In the third group psychosurgery was from the outset superior to shock therapy, and would have an increasing importance when it was learned how to avoid the side-effects of the operation. To this group belonged schizophrenics in the younger age groups with predominantly neurotic symptomatology; they were often wrongly diagnosed as neurotics, but closer observation revealed somatic delusions, bizarre expression of symptoms, and occasional hallucinatory experiences. Another group with a poor response to shock therapy but gratifying results following psychosurgery were cases of late schizophrenia with a predominantly paranoid symptomatology and well-preserved personality.

This speaker also discussed the question of relapses after shock therapy and psychosurgery respectively. The worst drawback in all shock treatments was the tendency to relapse. Even in adequately and successfully treated cases the rate of late relapses was considerable. But true relapses after leucotomy were rare. A leucotomized patient who had reached a certain equilibrium, even if the result was only fair, would not easily relapse.

Another difference to which he drew attention was in the patient's post-treatment amnesia for his symptoms. The insulin patient often had good insight and remembered most of his pathological experiences. The E.C.T. patient remembered little of his sickness. The leucotomized patient, if he lost his symptoms, had hardly any insight and even denied any improvement. The patient who had undergone shock therapy realized the difference and was usually very grateful; the leucotomized patient never. Both procedures left many basic questions open, but while something was known about the mode of action of psychosurgery nothing was known about the manner in which shock treatments worked.

Physiological Basis of Shock Therapy

Professor E. GELLHORN followed with a discussion of the physiological basis of shock therapy. His argument was that the procedures employed in shock therapy acted primarily through central autonomic discharges and through their effect on the cerebral cortex. In the experimental animal the techniques used in shock therapy for mental disease invariably excited the hypothalamic sympathetic system. He suggested that this state of heightened hypothalamic and medullary discharges resulted from two fundamentally different mechanisms. Insulin hypoglycaemia and barbiturate medication overcame the inhibition of cortical control; in convulsions induced by electric shock or metrazol direct excitation of these centres appeared to be the mechanism primarily involved. His theory was not that insulin coma and electrically or chemically induced convulsions acted through the secretion of adrenaline, but that these procedures greatly increased the reactivity of autonomic centres which in turn might influence the brain in such a manner as to restore normal behaviour.

Recent Techniques

A new technique in leucotomy was demonstrated by Dr. WALTER FREEMAN, of Washington. This was a modification of transorbital leucotomy, an operation which did not attract much attention until 1947 and, although a quick and safe method, gave disappointing results in the large number of chronic schizophrenic patients who were naturally considered for operation. Studies were therefore undertaken on the cadaver to ascertain whether the incisions could safely be extended so as to sever a large proportion of the radiation from the thalamus to the frontal pole. This proved easier than could have been expected. Merely by elevating the handle of the instrument when the point was in a certain position within the frontal lobe it was found possible to sever this radiation opposite the head of the caudate nucleus, and without additional danger to important vessels. By this new twist, which he termed the deep frontal cut, transorbital leucotomy could be made as extensive anatomically and as effective clinically as

IN BRONCHIAL ASTHMA

1600 : "*The specifics commonly used for moist asthmas are the roots of Cuckowpint, Hyssop, Horehound . . . . the syrup or volatile salt of Tobacco; Gum Ammoniac (above all) dissolved in vinegar. Compound Spirit of Verdigrise, dulcify'd Spirit of Nitre, Turpentine . . . . Balsam of Sulphur . . . . Juice of Woodlice with wine (an incomparable medicine) and the carminative spirit if the stomach be disordered.*"

MICHAEL ETMULLER, *Professor of Physic, Leipzig.*

Today : The "incomparable medicine" in bronchial asthma is 'Neo-Epinine.' Patients obtain relief without the discomfort of repeated injections, the side-effects of adrenaline, or the sleeplessness of ephedrine medication. 'Neo-Epinine' is administered sublingually as a compressed product or by oral inhalation as Spray Solution.

'NEO-EPININE'

ISOPROPYL *nor* ADRENALINE SULPHATE

BURROUGHS WELLCOME & CO. (THE WELLCOME FOUNDATION LTD.) LONDON

Why 'Ribena' in Gum Infections?

Because the satisfactory results from clinical tests with Ribena have confirmed the belief that hypovitaminosis C predisposes to defective dentition and gum infections. Because, moreover, *natural* vitamin C, in the form of blackcurrant syrup, has been shown by practical experience to be a most valuable adjunct to local therapy in ulcerative stomatitis. Further, more specific, information gladly supplied to members of the medical profession.

Ribena is the pure undiluted juice of fresh ripe blackcurrants with sugar, in the form of a delicious syrup. Being freed from all cellular structure of the fruit, it will not upset the most delicate stomach. It is particularly rich in *natural* vitamin C (not less than 20 mgm. per fluid ounce) and associated factors.

Correspondence

Research in Renal Disease

SIR,—It is gratifying to receive, both in your columns and privately, such encouraging support for the plan outlined in my letter (May 21, p. 910) to secure for nephrology the status of a major medical specialty and the facilities for developing it in the best way—in particular, university recognition and the foundation of one or more institutes of nephrology.

Many specialties are now in the queue for reorganization as independent but integrated regional or national special services, and I venture to suggest that none has greater claim to priority than nephrology: first, because renal disease is probably the commonest cause of death in this country; secondly, because there is no organization for dealing on an adequate scale with the problems of patients suffering from these disorders, whereas most other specialties have some kind of organization which enables them to function, if inadequately; and thirdly, because of the exceptionally long period required for the training of personnel.

Provided the will is present there does not seem to be any insuperable difficulty in making a modest beginning forthwith by establishing at least one model renal centre of this kind, and it is to be hoped that action along these lines will speedily be taken.

A unique opportunity is now offered for establishing on a sound basis what is virtually, as an organized discipline, a new specialty. Unless it is seized there is a danger that hospitals, not necessarily of the most suitable type, will set up token units of a few beds in charge of those without adequate training and experience, and the service will be discredited at the outset. It is within my knowledge that several units of this kind are already in contemplation.

While opportunities should never be denied those wishing to take a special interest in any branch of medicine, it is essential, if the best candidates are to be attracted to the new service, that the staff should be recruited from among those who have fitted themselves by training for this special work.

I have been asked why in my previous letter I stated that nephrology should be based on a university postgraduate renal hospital and school, and not on an undergraduate teaching hospital as are most other specialties. The reason is that in my experience the highest standards of practice, nursing, and routine laboratory work in a specialty so dependent upon accurate detail as nephrology are unattainable in a general hospital, where the sharing of ancillary services is inevitable; and still less in an undergraduate teaching hospital, where in addition the emphasis must lie on general principles rather than on scientific detail and advanced technique.

At the same time there are aspects of research in renal disease that can best be approached in a general hospital. It is important, moreover, that undergraduates and student nurses, as part of their general training, should see in a properly organized department run by experts what can and what cannot be done for patients suffering from renal disease. In my view, therefore, every first-class general hospital should have its own largely autonomous and self-contained renal unit linked with, and staffed by, the central renal hospital and school. Organized in this way, every unit in the renal service would be brought not only directly but effectively under university influence.—I am, etc.,

London, W.1. A. A. OSMAN.

Reform in Medical Education

SIR,—Your educational number and the letter of Dr. R. D. Lawrence (September 10, p. 594) are welcome indications of the realization of the necessity for radical reform in medical education in this country. Dr. Lawrence rightly remarks that teaching ability is a minor consideration in appointments to a teaching hospital. His outlook, limited as it is by tradition and practice, leads him to suggest that the natural source of medical teachers arises amongst the registrar type.

Now it is universally admitted that one of the most important points in the teaching of clinical medicine is the recognition of disease in its earliest manifestations. One wonders how often the registrar type sees disease in its early stages. The most successful clinical teacher is he who can help the student to hear the faint voice of the patient's tissues talking through the patient's voice, and to continue to listen to that voice ignoring the siren voice of the patient's mother and the strident voice of the patient's wife.

The natural source of this ability is the type of doctor who is accustomed to seeing disease in its earliest form, and who has learned to ignore the fond but foolish mother and the clanking of the matrimonial ball-and-chain. He is, of course, the experienced general practitioner, and no medical institution would be complete without a corps of teaching practitioners who would give the benefit of their valuable experience to medical students, the majority of whom are destined to follow in the footsteps of their teachers.—I am, etc.,

Luton. C. BASTIBLE.

Distinction Awards

SIR,—It is true that private practice still remains at the disposal of those who feel that their merit deserves remuneration, as we are reminded in a letter on distinction awards (August 27, p. 484). I believe it would sorely tax the wisest to diagnose this attribute in a colleague, and indeed the word is incapable of precise definition. Grades of merit, failing more accurate definition, are therefore impracticable.

The assumption that it is merit that wealthy people are peculiarly capable of diagnosing and prepared to reward is, of course, no more true than that a full-time hospital doctor is necessarily less meritorious than his part-time colleague.—I am, etc.,

Lepton, near Huddersfield. GEORGE JENNINGS.

SIR,—Dr. F. M. R. Walshe and his supporters have failed to find an equitable method of assessing merit. To conclude from this failure that available funds must be handed back to the Treasury is as feeble as it is improvident; to condone, by reason of this failure, a standard salary to all consultants is to surrender to the commonplace mind, which Dr. Walshe once attacked so brilliantly.

Distinction in medicine may be interpreted now, as ever, as distinction in professional service to the community. Financial reward in proportion to the value of such service is both attractive and just; the budding consultant needs some such stimulus, and will not be misled by hocus-pocus about the rewards to be gained in private practice in the future.

I agree with your correspondents who reject the idea that consultants (or any committee of them) can offer a competent or unbiased opinion upon their own or their colleagues' value to the community, and it is this aspect alone which threatens the profession with internal strife and undesirable practices. In an attempt to be constructive I wish to draw attention to a body of reasonably impartial observers who are available to effect the necessary comparisons, and whose assessments have decided consultants' monetary rewards in the past to the apparent satisfaction of all parties. I submit that general practitioners are still in a unique position to assess all of the following essential components of their consultants' service to the public: (1) Clinical and technical competence. (2) Industry. (3) Sense of responsibility and courtesy to colleagues—e.g., promptness and quality of reporting to the family doctor. (4) Maintenance of morale in hospital, as shown, for example, by readiness of "firms" to accept cases at night. (5) Efficiency of out-patient organization and overhaul of waiting-lists. The higher the standard reached in these aspects of service, for each of which I hold the consultant responsible, the greater the benefit to the public and the greater the entitlement to reward from the public purse.

My suggestion is that the awards be made in proportion to the votes gained in the respective departments and specialties at an area ballot in which G.P.s will record their preferences. Sums of money should be set aside for distribution to teachers, research workers, and other specialists whom the family doctor is not competent to compare. Teachers could be awarded in

proportion to the votes of their students, research workers by a body elected by themselves for the purpose, and workers such as anaesthetists by surgeons or others competent to assess them. The ballots should be held every, say, two years, in order to keep the recipients on their toes.

It will be appreciated that this suggestion does not involve any radical change. Consultants will be supported by those they serve well, as in the past, and the die-hards should experience no anguish in adapting themselves to what would merely be a novel method of expression of the family doctor's approval.—I am, etc.,

Sheffield, 3. B. BURNS.

SIR,—In your issue of September 3 (p. 545) you published two letters on the subject of distinction awards. In one Dr. C. C. Beatty suggests—rather flippantly—the possibility of a points system; in the other Mr. F. Ridley not only treats the question with the seriousness it deserves but draws up a detailed plan.

I am gratified to see that in section 1 of this plan he awards marks for an arts degree. Never has a high standard of culture been more needed by consultants than to-day. The standard attained by a minister should not be unattainable by any consultant worthy of the name.

In section 2 it is surprising—or is it in these days when the mighty are being put down from their seat and the humble exalted?—to find the undergraduate teaching hospital rated lower than the postgraduate teaching hospital. Mr. Ridley's outlook is in keeping with the times.

As regards the marks he would award to local presidents and secretaries of medical academic societies, I foresee a hitherto unknown attendance and enthusiasm on the part of their members if elevation to the presidency and secretaryship may mean a higher category and a greatly increased income. There are, I think, other and less desirable consequences likely to ensue, but their nature can be left to the imaginations of the readers of this correspondence.

Section 3 provides a new version of an old adage, for should Mr. Ridley's plan be found acceptable to the authorities the pen will prove thenceforth far mightier than the scalpel and the stethoscope. Already an aspiring consultant can scarcely hope to gain recognition unless he publishes thousands and thousands of words—usually of no world-shattering importance—in accredited medical journals. One's reason reels when one contemplates the outpouring of words there is certain to be when he recognizes that his publication may qualify him to receive as many marks as he can win by spending fifteen years or more on the staff of an undergraduate teaching hospital.

At first my heart went out in sympathy towards the members of the awards committee, as in my mind's eye I watched them reading closely all the published work of all consultants; but then I saw a better way. Who after all is best qualified to judge the value of a contribution to the press? Surely its author. In such a case let him assess his own marks. Thus will the awards committee be relieved of this part of its onerous and invidious burden and an egalitarian spirit be fostered.

A further sign of the times is the fact that Mr. Ridley, so far as I can see, attaches no value to such vexatious and intangible considerations as clinical acumen and judgment, or operative skill, which the old-fashioned generation to which I belong used to think of some importance in the make-up of a consultant. Nevertheless, he may be right, for under the new regime they would seem destined to be increasingly discounted as time marches on.—I am, etc.,

London, W.1 J. W. LINNELL.

SIR,—Sir Henry Dale has recently written, "Science is one of the human activities which can only live in freedom. If anyone would know what would happen to it in the stranglehold of official tyranny, he should read this terrible indictment." This is part of an introduction to John Langdon-Davies's book on the Lysenko affair. Communistic science is a branch of ideological politics.

Dr. Boldero's recent letter to the *British Medical Journal* (September 10, p. 594) is fundamentally an expression of similar, although less complete, servitude to the State, and the same acquiescent attitude has been true of those who have taken his view that medicine as such must surrender its essential freedom to political considerations. It is not without significance that many prominent members of the profession holding this view, and who have helped to enforce it, have been deans, and very successful deans, of medical schools. The whole outlook and training of a dean is one of honest and faithful subservience to an institution. That of a scientist is independence, and, if necessary, defiance of authority.

Sir Hartley Shawcross has recently spoken very forthrightly against the nationalization of the legal profession, indicating that such a step would be towards totalitarianism. Law, however, is essentially an administrative activity and is not founded on continually growing, living sciences. But medicine, in whose independence Sir Hartley is not so interested, is founded on physiology, chemistry, physics, psychology, and many other live activities of human civilization and development. It was all the more essential that medicine, which in itself is partly, at any rate, a branch of active science, should not have fallen under the domination of the State.

Science in the past has frequently had to hold up its head and indeed suffer in opposition to the political powers of the day. Galileo was one example, and it was Pasteur who said, "*Tout le monde est contre moi.*" This view of medical scientific freedom is one that has been renounced by Dr. Boldero and those who have felt and acted as he has done, and who have given precedence to political considerations. The present difficulties, of which that of the distinction awards is at the moment most prominent, are merely examples of further steps into the mire, and are unavoidable by those who have strayed from the sound way of following principles rather than expediency. If medicine is to save itself from the political quagmire it will have to retrace its steps painfully and with great difficulty, turning its eyes again to those fixed principles and steadily refraining from following political will-o'-the-wisps.—I am, etc.,

London, W.1. GEOFFREY BOURNE.

SIR,—The battle of distinction awards has been won and lost. After full debates in correspondence columns and medical committees it seems clear that a majority of consultants do not propose to offer effective opposition to their imposition. But the issue was closer even than it now seems in retrospect, and many of the majority only reluctantly came to their decision and after many hesitations. What of the minority? That their case cannot be dismissed by superficial explanations is proved by the very existence of a powerful revolt against increased monetary rewards, led by men of whom many might legitimately be regarded as possible recipients of such rewards. The arguments influencing the minority have been variable, those most stressed being the practical difficulties of distinguishing between true distinction and garnished mediocrity, and the fear that the scheme would widen divisions both among consultants themselves and in the profession at large.

Although less clearly formulated, I believe that two other powerful arguments have exerted even greater influence. While no financiers, we suspect that in the present state of the country and the world the theory of financial rewards of the whole health scheme rests on fallacious foundations. And, more important still, we believe that the almost complete reliance on the State which the acceptance of the distinction awards implies means the disappearance of an independent medical profession. If such is our faith, what should now be our action? I suggest we can do no other but individually inform the awards committee that we do not wish to be considered and request that our names be so listed when the awards are published. Thus we may provide a leaven of sacrifice which will preserve the soul of medicine.—I am, etc.,

London, W.1. DAVID H. PATEY.

SIR,—It is of interest to record how very closely the opinions of the consultants of a non-teaching group on distinction awards agree with those of your Leeds correspondents (August 27, p. 484). It was the unanimous view of the Medical Advisory Committee of the Chelmsford Group that the reward for

exceptional merit for the part-time consultant would be most accurately assessed and most suitably adjusted by the maintenance of reasonable facilities for private practice, and that for those consultants undertaking hospital duties of similar responsibility the correct method of remuneration was "the rate for the job."

Distinction awards based on past records assessed by a committee without personal knowledge of the consultant or his present work were generally regarded as most undesirable. They would be embarrassing to the recipient and unfair to colleagues with precisely similar duties. Even if this system was desirable it would be manifestly impossible to allocate the awards with justice.

I do not think these views are exceptional. They may be taken as a random sample which represents the opinion of part-time consultants throughout the country, and it is a calamity that this scheme, full of dangerous potentialities, has been accepted without obtaining the opinion of those most vitally concerned.

The continued existence of the part-time specialist presupposes legitimate opportunities for private practice. At the present time this is slowly being reduced by the very high charges made for private accommodation in hospitals and the progressive conversion of such accommodation to other purposes. This policy calls for review.
